

- In the setting of coronary artery bypass graft (CABG) surgery [see Warnings and Precautions (5.1)]

5 WARNINGS AND PRECAUTIONS

Clinical trials of severe COX-2 selective and nonselective NSAIDs of up to three years duration have shown an increased risk of serious cardiovascular (CV) thrombotic events, including myocardial infarction (MI) and stroke, which can be fatal. Based on available data, it is unclear that the risk for CV thrombotic events is similar for all NSAIDs. The relative increase in serious CV thrombotic events over baseline conferred by NSAID use appears to be similar in those with and without known CV disease or risk factors for CV disease. However, patients with existing CV disease or other risk factors for CV disease may be at greater absolute risk of serious CV thrombotic events, due to their increased baseline rate. Some observational studies found that this increase in risk of serious CV thrombotic events began as early as the first weeks of treatment. The increase in CV thrombotic risk has been observed most consistently in higher doses.

There is no consistent evidence that concurrent use of aspirin mitigates the increased risk of serious CV thrombotic events associated with NSAID use. The concurrent use of aspirin and an NSAID, such as meloxicam, increases the risk of serious gastrointestinal (GI) events [see Warnings and Precautions (5.2)].

Status Post Coronary Artery Bypass Graft (CABG) Surgery

the first 10-14 days following CABG surgery found an increased incidence of myocardial infarction and stroke. NSAIDs are contraindicated in the setting of CABG [see Contraindications (4)].

Post-MI Patients

patients treated with NSAIDs in the post-MI period were at increased risk of reinfarction, CV-related death, and all-cause mortality beginning in the first week of treatment. In this same cohort, the incidence of death in the first year post-MI was 20 per 100 person years in NSAID-treated patients compared to 12 per 100 person years in non-NSAID exposed patients. Although the absolute rate of death declined somewhat after the first year post-MI, the increased relative risk of death in NSAID users persisted over at least the next four years of follow-up.

5.2 Gastrointestinal Bleeding, Ulceration, and Perforation

including inflammation, bleeding, ulceration, and perforation of the esophagus, stomach, small intestine, or large intestine, which can be fatal. These serious adverse events can occur at any time, with or without warning symptoms, in patients treated with NSAIDs. Only one in five patients who develop a serious upper GI adverse event on NSAID therapy is symptomatic. Upper GI ulcers, gross bleeding, or perforation caused by NSAIDs occurred in approximately 1% of patients treated for 3-6 months, and in about 2-4% of patients treated for one year. However, even short-term NSAID therapy is not without risk.

Risk Factors for GI Bleeding, Ulceration, and Perforation

had a greater than 10-fold increased risk for developing a GI bleed compared to patients without these risk factors. Other factors that increase the risk of GI bleeding in patients treated with NSAIDs include longer duration of NSAID therapy; concomitant use of oral corticosteroids, aspirin, anticoagulants, or selective serotonin reuptake inhibitors (SSRIs); smoking; use of alcohol; older age; and poor general health status. Most postmarketing reports of fatal GI events occurred in elderly or debilitated patients. Additionally, patients with advanced liver disease and/or coagulopathy are at increased risk for GI bleeding.

Strategies to Minimize the GI Risks in NSAID-treated patients:

- Avoid administration of more than one NSAID at a time.
- Avoid use in patients at higher risk unless benefits are expected to outweigh the increased risk of bleeding. For such patients, as well as those with active GI bleeding, consider alternate therapies other than NSAIDs.
- Remain alert for signs and symptoms of GI ulceration and bleeding during NSAID therapy.
- If a serious GI adverse event is suspected, promptly initiate evaluation and treatment, and discontinue Meloxicam until a serious GI adverse event is ruled out.
- In the setting of concomitant use of low-dose aspirin for cardiac prophylaxis, monitor patients more closely for evidence of GI bleeding [see Drug Interactions (7)].

5.3 Hepatotoxicity

been reported in approximately 1% of NSAID-treated patients in clinical trials. In addition, rare, sometimes fatal, cases of severe hepatic injury, including fulminant hepatitis, liver necrosis, and hepatic failure have been reported.

Inform patients of the warning signs and symptoms of hepatotoxicity (e.g., nausea, fatigue, lethargy, diarrhea, pruritus, jaundice, right upper quadrant tenderness, and "flu-like" symptoms). If clinical signs and symptoms consistent with liver disease develop or

5.4 Hypertension

hypertension, either of which may contribute to the increased incidence of CV events. Patients taking angiotensin converting enzyme (ACE) inhibitors, thiazide diuretics, or loop diuretics may have impaired response to these therapies when taking NSAIDs [see Drug Interactions (7)].

Monitor blood pressure (BP) during the initiation of NSAID treatment and throughout the course of therapy.

5.5 Heart Failure and Edema

controlled trials demonstrated an approximately two-fold increase in hospitalizations for heart failure in COX-2 selective-treated patients and nonselective NSAID-treated patients compared to placebo-treated patients. In a Danish National Registry study of patients with heart failure, NSAID use increased the risk of MI, hospitalization for heart failure, and death.

Avoid the use of Meloxicam in patients with severe heart failure unless the benefits are

expected to outweigh the risk of worsen-

5.6 Renal To

Long-term administration of NSAIDs, including Meloxicam, has resulted in renal papillary necrosis, renal insufficiency, acute renal failure, and other renal injury.

decompensation. Patients at greatest risk of this reaction are those with impaired renal function, dehydration, hypovolemia, heart failure, liver dysfunction, those taking diuretics and ACE inhibitors or ARBs, and the elderly. Discontinuation of NSAID therapy is usually followed by recovery to the pretreatment state.

Correct volume status in dehydrated or hypovolemic patients prior to initiating Meloxicam. Monitor renal function in patients with renal or hepatic impairment, heart failure, dehydration, or hypovolemia during use of Meloxicam [see Drug Interactions (7)]

Hyperkalemia

5.7 Anaphylactic Reactions

known hyper-sensitivity to minkowski, and it products well as a minkowski disease [see Contraindications (4) and Warnings and Precautions (5.8)].

A subpopulation of patients with asthma may have aspirin-sensitive asthma which may include chronic rhinosinusitis complicated by nasal polyps; severe, potentially fatal bronchospasm; and/or intolerance to aspirin and other NSAIDs. Because cross-

5.9 Serious Skin Reactions

(TEN), which can be fatal. These serious events may occur without warning. Inform patients about the signs and symptoms of serious skin reactions, and to discontinue the use of Meloxicam at the first appearance of skin rash or any other sign of hypersensitivity. Meloxicam is contraindicated in patients with previous serious skin reactions to NSAIDs [see Contraindications (4)].

5.11 Hematologic Toxicity

blood loss, fluid retention, or an incompletely described effect on erythropoiesis. If a patient treated with Meloxicam has any signs or symptoms of anemia, monitor hemoglobin or hematocrit.

5.12 Masking of Inflammation

6.12 Laboratory Monitoring

6 ADVERSE REACTIONS

- Cardiovascular Thrombotic Events [see Boxed Warning and Warnings and Precautions (5.1)]

- Anaphylactic Reactions [see

6.1 Clinical Trials Experience

The Mexican Race 2/3 clois

treated with Meloxicam 15 mg/day. Meloxicam at these doses was administered to 661 patients for at least 6 months and to 312 patients for at least one year. Approximately 10,500 of these patients were treated in ten placebo- and/or active-controlled osteoarthritis trials and 2363 of these patients were treated in ten placebo- and/or active-controlled rheumatoid arthritis trials. Gastrointestinal (GI) adverse events were the most frequently reported adverse events in all treatment groups across Meloxicam

safety of Meloxicam with placebo.

Table 1a depicts adverse events that occurred in $\geq 2\%$ of the Meloxicam treatment groups in a 12-week placebo- and active-controlled osteoarthritis trial.

Table 1b depicts adverse events that occurred in $\geq 2\%$ of the Meloxicam treatment groups in two 12-week placebo-controlled rheumatoid arthritis trials.

Higher doses of Meloxicam (22.5 mg and greater) have been associated with an increased risk of serious GI events; therefore, the daily dose of Meloxicam should not exceed 15 mg.

Pediatrics
Bursitis and Bursitis Course: Juvenile Rheumatoid Arthritis (JRA)

Pauciarticular and Polyarticular Course Juvenile Rheumatoid Arthritis (JRA)

Three hundred and eighty-seven patients with pauricular and/or polymorphic course JRA were exposed to Mefenamic acid with dosages ranging from 0.125 to 0.375 mg/kg per day in three clinical trials. These studies consisted of two 12-week multicenter, double-blind, randomized trials (one with a 12-week open-label extension and one with a 40-week open-label extension) and one open-label PM study. The adverse events observed in these pediatric studies with Mefenamic acid were similar in nature to the adult clinical trial experience, although there were differences in frequency. In particular, the following most common adverse events, abdominal pain, vomiting, diarrhea, headache, and paresthesia, were more common in the pediatric than in the adult trial. Rash was reported in 10% of patients in the pediatric studies compared with 1% in the adult trial. No events were identified during the course of the trials. The adverse events did not demonstrate an age- or gender-specific subgroup effect.

The following is a list of adverse drug reactions occurring in <2% of patients receiving Meloxicam in clinical trials involving approximately 16,200 patients.

Study in a Whale	stergic reaction, face edema, fatigue, fever, hot flashes, malaise, syncope, weight decrease, weight increase
Cardiovascular	angina pectoris, cardiac failure, hypertension, myocardial infarction, vasculitis
Central and Peripheral Nervous System	chondrosarcoma, parosmia, tonic-clonic
Gastrointestinal	colitis, dry mouth, duodenal ulcer, dysphagia, gastritis, gastric ulcer, gastroprolongation, gastroresistant hemorrhage, hematemesis, hemorrhage, duodenal ulcer, hemorrhagic gastritis, ulcer, intestinal perforation, nausea, parosmia, perforated duodenal ulcer, perforated gastric ulcer, stomatitis
Heart Rate and Rhythm	atrial fibrillation, tachycardia
Hematologic	hematuria, purpura, thrombocytopenia
Use and Abuse System	ALT increased, AST increased, bilirubemia, CPK increased, hepatitis
Metabolic and Nutritional	dehydration
Psychiatric	abnormal dreams, anxiety, apoplexy increased, confusion, depression, hallucinations, mania, somnolence
Skin and Appendages	dermatitis, foot/toe/toe/nail degeneration, pruritus, sweating increased, urticaria
Special Senses	abnormal vision, conjunctivitis, taste perversion, vertigo
Urogenital	hematuria, hemoglobinuria, hemolysis, increased creatinine, hematuria, renal failure

6.2 Post Marketing Experience

The following adverse reactions have been identified during post approval use of Telivon. Because these reactions are reported worldwide from a population of diverse ethnicities, it is always possible that ethnicity may establish a causal relationship to drug exposure. Decisions about whether to include an adverse event from spontaneous reports in labeling are typically based on one or more of the following factors: (1) seriousness of the event, (2) number of reports, or (3) strength of causal relationship to the drug. Adverse reactions reported in worldwide post marketing surveillance include: anaphylaxis, acute respiratory depression, agranulocytosis, alterations in mood (such as mood elevation); anaphylactoid reactions including shock; anhydria; multiiforme; exfoliative dermatitis; interstitial nephritis; jaundice; liver failure; Stevens-Johnson syndrome; toxic epidermal necrolysis, and infertility female.

7 DRUG INTERACTIONS

See Table 3 for clinically significant drug interactions with meloxicam. See also Warnings and Precautions (5.2, 5.6, 5.11) and Clinical Pharmacology (12.3) .

Table 3 Clinically Significant Drug Interactions with Meloxicam

	<p>Drugs that interfere with Hemostasis</p> <p>Warfarin</p> <p>Mexican and anticoagulant drugs as warfarin have a synergistic effect on bleeding. The concomitant use of mexican and anticoagulant have an increased risk of serious bleeding compared to the use of either drug alone. Concomitant use of mexican and warfarin increases the risk of bleeding. Cross-control and other epidemiological studies showed that concomitant use of drugs that interfere with warfarin response and an NSAID may potentiate the risk of bleeding more than an NSAID alone.</p> <p>Aspirin</p> <p>Monitor patients with concomitant use of Mexican with antiplatelets (e.g., warfarin), antiplatelet agents (e.g., aspirin), selective serotonin reuptake inhibitors (SSRIs), and serotonin norepinephrine reuptake inhibitors (SNRIs) for signs of bleeding [see Warnings and Precautions] (5.1.1).</p> <p>NSAIDs</p> <p>Controlled clinical studies showed that the concomitant use of Mexican and analgesic drugs does not produce any greater therapeutic effect than the use of NSAIDs alone. In a clinical study, the concomitant use of an NSAID and aspirin was associated with a significantly increased incidence of adverse reactions as compared to use of the NSAID alone [see Warnings and Precautions] (5.1.2).</p> <p>ACE Inhibitors</p> <p>Concomitant use of Mexican and ACE inhibitors or angiotensin receptor blockers (ARBs) may result in a decrease in the blood pressure response to treatment with ACE inhibitors or ARBs. Mexican is not a substitute for low dose aspirin for cardiovascular protection.</p> <p>Angiotensin Receptor Blockers, or ARBs</p> <p>Patients may develop the antihypertensive effect of angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), or beta-blockers [including propranolol]. Patients who are already volume-depleted (including those on diuretic therapy), or have renal impairment, coadministration of mexican with ACE inhibitors or ARBs may result in deterioration of renal function, including possible acute renal failure. These effects are usually reversible.</p> <p>ACE Inhibitors</p> <p>During concomitant use of Mexican and ACE inhibitors, ARBs, or beta-blockers, monitor blood pressure to ensure that the desired blood pressure is obtained. During concomitant use of Mexican and ACE inhibitors or ARBs in patients who are elderly, volume-depleted, or have impaired renal function, monitor for signs of worsening renal function [see Warnings and Precautions] (5.6). When these groups are administered concomitantly, patients should be adequately hydrated and renal function should be monitored and adjusted as needed.</p> <p>Diuretics</p> <p>United states, as well as post-marketing observations, showed that NSAIDs reduced the natriuretic effect of short-acting (e.g., furosemide) and middle-acting diuretics in some patients. This effect has been attributed to the NSAID inhibition of renal prostaglandin synthesis. However, studies with furosemide and mexican have not demonstrated a reduction in natriuretic effect. Furosemide single and multiple dose pharmacokinetics and pharmacokinetics are not affected by multiple doses of mexican.</p> <p>Diuretics</p> <p>During concomitant use of Mexican with diuretic agents, monitor patients for signs of worsening renal function, including possible acute renal failure. These effects are usually reversible.</p> <p>Alcohol</p> <p>NSAIDs have been shown to increase plasma ethanol levels and to inhibit the renal elimination of ethanol. The mean ethanol blood concentration increased 35% and the renal clearance decreased by approximately 20%. This effect has been attributed to NSAID inhibition of renal prostaglandin synthesis [see Clinical Pharmacology] (12.3).</p> <p>Thrombolytics</p> <p>During concomitant use of Mexican and thrombolytic agents, monitor patients for signs of thrombotic toxicity.</p> <p>Metformin</p> <p>Concomitant use of Mexican and metformin may increase the risk for metformin toxicity (e.g., lactic acidosis, hypoglycemia, renal dysfunction).</p> <p>Metformin</p> <p>Concomitant use of Mexican and metformin, monitor patients for metformin toxicity.</p> <p>Cyclosporine</p> <p>Concomitant use of Mexican and cyclosporine may increase cyclosporine nephrotoxicity.</p> <p>Cyclosporine</p> <p>During concomitant use of Mexican and cyclosporine, monitor patients for signs of worsening renal function.</p> <p>NSAIDs and Salicylates</p> <p>Concomitant use of mexican with other NSAIDs or salicylates (e.g., ethacrynic acid) increases the risk of GI toxicity, with little or no increase in efficacy [see Warnings and Precautions] (5.2.3).</p> <p>Concomitant use of mexican with other NSAIDs or salicylates is not recommended.</p> <p>Pain relievers</p> <p>Concomitant use of Mexican and pain relievers may increase the risk of pain reliever-associated hypoglycemia, renal, and GI toxicity (see the pain reliever prescribing information).</p> <p>Pain relievers</p> <p>During concomitant use of Mexican with pain relievers (e.g., acetaminophen), monitor for hypoglycemia, renal, and GI toxicity.</p> <p>Pain relievers</p> <p>Patients taking mexican should abstain from alcohol for at least two days before, the day of, and two days following pain reliever administration.</p> <p>Pain relievers</p> <p>In patients with creatinine clearance below 45 mL/min, the concomitant administration of mexican with pain relievers is not recommended.</p>
--	---

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary
Use of NSAIDs, including Meloxicam, during the third trimester of pregnancy increases the risk of premature closure of the fetal ductus arteriosus. Avoid use of NSAIDs, including Meloxicam, in pregnant women starting at 30 weeks of gestation (third trimester) [see Warnings and Precautions (5.10)].

There are no adequate and well-controlled studies of Minoxidil in pregnant women. Data from observational studies regarding potential embryofetal risk of NSAQ use in women in the first or second trimesters of pregnancy are inconclusive. In the general U.S. population, all clinically recognized pregnancies, regardless of drug exposure, have a background rate of 2-4% for major malformations, and 15-20% for pregnancy loss. In animal reproduction studies, major malformations were observed in rats and rabbits treated during the period of organogenesis with minoxidil at oral doses equivalent to 1.6 times the human dose. In rats, increased incidence of cleft palate and increased incidence of septal heart defects were observed in rabbits treated throughout embryogenesis with minoxidil at an oral dose equivalent to 78-times the MHRD. In pre- and post-natal reproduction studies, there was an increased incidence of dystocia, delayed parturition, and decreased offspring survival at 0.08-times the MHRD of minoxidil in rats. In rabbits, increased incidence of stillbirths and decreased offspring survival at 0.08-times the MHRD at an oral dose equivalent to 2.6 and 26-times the MHRD (see Data

Based on animal data, prostaglandins have been shown to have an important role in endometrial vascular permeability, blastocyst implantation, and decidualization. In animal studies, administration of prostaglandin synthetase inhibitors, such as meloxicam, resulted in increased pre- and post-implantation loss.

Clinical Considerations

Labor or Delivery
There are no studies on the effects of Meloxicam during labor or delivery. In animal studies, NSAIDs, including meloxicam, inhibit prostaglandin synthesis, cause delayed parturition, and increase the incidence of stillbirth.

Data

Meloxicam was not teratogenic when administered to pregnant rats during fetal organogenesis at oral doses up to 4 mg/kg/day (2.6-fold greater than the MRHD of 1 mg of Meloxicam based on BSA comparison). Administration of meloxicam to pregnant

rabbits throughout embryogenesis produced an increased incidence of septal defects in the heart at an oral dose of 60 mg/kg/day (78-fold greater than the MRHD based on 1 comparison). The no effect level was 20 mg/kg/day (26-fold greater than the MRHD based on BSA conversion). In rats and rabbits, embryo lethality occurred at oral

meloxicam doses of 1 mg/kg/day and 5 mg/kg/day, respectively (0.65 and 6.5-fold

renal impairment. Total drug plasma concentrations of meloxicam decreased and total clearance of meloxicam increased with the degree of renal impairment while free AUC values were similar in all groups. The higher meloxicam clearance in subjects with renal impairment may be due to increased fraction of ultrafast meloxicam which is available for hepatic metabolism and subsequent excretion. No dosage adjustment is necessary in patients with mild to moderate renal impairment. Patients with severe renal impairment have not been adequately studied. The use of Meloxicam in subjects with severe renal impairment is not recommended [see Dosage and Administration (2.3), Warnings and Precautions (5.6) and Use in Specific Populations (8.7)].

Hemodialysis

Following a single dose of meloxicam, the free C_{max} plasma concentrations were higher in patients with renal failure on chronic hemodialysis (1% free fraction) in comparison to healthy volunteers (0.3% free fraction). Hemodialysis did not lower the total drug concentration in plasma; therefore, additional doses are not necessary after hemodialysis. Meloxicam is not dialyzable [see Dosage and Administration (2.3) and Use in Specific Populations (8.7)].

Drug Interactions Studies

Aspirin: When NSAIDs were administered with aspirin, the protein binding of NSAIDs were reduced, although the clearance of free NSAID was altered. When Meloxicam is administered with aspirin (1000 mg three times daily) to healthy volunteers, it tended to increase the AUC (10%) and C_{max} (4%) of meloxicam. The clinical significance of this interaction is not known. See Table 3 for clinically significant drug interactions of NSAIDs with aspirin [see Drug Interactions (7.1)].

Cholestyramine: Pretreatment for four days with cholestyramine significantly increased the clearance of meloxicam by 50%. This resulted in a decrease of C_{max} from 19.3 hours to 12.5 hours, and a 35% reduction in AUC. This suggests the existence of a secretory pathway for meloxicam in the gastrointestinal tract. The clinical relevance of this interaction has not been established.

Cimetidine: Concurrent administration of 200 mg cimetidine four times daily did not alter the single-dose pharmacokinetics of 30 mg meloxicam.

Digoxin: Meloxicam 15 mg once daily for 7 days did not alter the plasma concentration profile of digoxin after β -acetylglucoside administration for 7 days at clinical doses. In vitro binding found no protein binding drug interaction between digoxin and meloxicam.

Lithium: In a study conducted in healthy subjects, mean pre-dose lithium concentration and AUC were increased by 21% in subjects receiving lithium doses ranging from 804 to 1072 mg twice daily with meloxicam 15 mg QD every day as compared to subjects receiving lithium alone [see Drug Interactions (7)].

Methotrexate: A study in 13 rheumatoid arthritis (RA) patients evaluated the effects of multiple doses of meloxicam on the pharmacokinetics of methotrexate taken weekly. Meloxicam did not have a significant effect on the pharmacokinetics of single doses of methotrexate. In vitro, methotrexate did not displace meloxicam from its human serum binding sites [see Drug Interactions (7)].

Warfarin: The effect of meloxicam on the anticoagulated effect of warfarin was studied in a group of healthy subjects receiving daily doses of warfarin that produced an INR (international normalized ratio) between 1.2 and 1.8. In these subjects, meloxicam did not alter warfarin pharmacokinetics and the average anticoagulant effect of warfarin as determined by prothrombin time. However, one subject showed an increase in INR from 1.5 to 2.1. Caution should be used when administering Meloxicam with warfarin since patients on warfarin may experience changes in INR and an increased risk of bleeding complications when a new medication is introduced [see Drug Interactions (7)].

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Carcinogenesis

There was no increase in tumor incidence in long-term carcinogenicity studies in rats (104 weeks) and mice (99 weeks) administered meloxicam at oral doses up to 0.8 mg/kg/day in rats and up to 8.0 mg/kg/day in mice (up to 0.5 and 2.6 times, respectively, the maximum recommended human dose [MRHD]) of 15 mg/day Meloxicam based on body surface area (BSA) comparison).

Mutagenesis

Meloxicam was not mutagenic in an Ames assay, or clastogenic in a chromosome aberration assay with human lymphocytes and an in vivo micronucleus test in mouse bone marrow.

Impairment of Fertility

Meloxicam did not impair male and female fertility in rats at oral doses up to 8 mg/kg/day in males and 5 mg/kg/day in females up to 1.6- and 1.2 times greater, respectively, than the MRHD based on BSA comparison).

14 CLINICAL STUDIES

14.1 Osteoarthritis and Rheumatoid Arthritis

The use of Meloxicam for the treatment of the signs and symptoms of osteoarthritis of the knee and hip was evaluated in a 12-week, double-blind, controlled trial. Meloxicam (0.75 mg, 1.5 mg, and 15 mg daily) was compared to placebo. The four primary endpoints were investigator's global assessment, patient global assessment, patient pain assessment, and total WOMAC score (a self-administered questionnaire addressing pain, function, and stiffness). Patients on Meloxicam 7.5 mg daily and Meloxicam 15 mg daily showed significant improvement in each of these endpoints compared with placebo.

The use of Meloxicam for the management of signs and symptoms of osteoarthritis was evaluated in a double-blind, active-controlled trial, outside the U.S., from 8 weeks to 6 months' duration. In these trials, the efficacy of Meloxicam, in doses of 7.5 mg/day and 15 mg/day, was comparable to naproxen 20 mg/day and celecoxib 50-100 mg/day and consistent with the efficacy seen in the U.S. trial.

The use of Meloxicam for the treatment of the signs and symptoms of rheumatoid arthritis was evaluated in a 12-week, double-blind, controlled multinational trial. Meloxicam (0.75 mg, 1.5 mg, and 22.5 mg daily) was compared to placebo.

The primary endpoint in this study was the ACR20 response rate, a composite measure of clinical, laboratory, and functional measures of RA response. Patients receiving Meloxicam 7.5 mg and 15 mg daily showed significant improvement in the primary endpoint compared with placebo. No incremental benefit was observed with the 22.5 mg dose compared to the 15 mg dose.

14.2 Juvenile Rheumatoid Arthritis (JRA) Pauciarticular and Polyarticular Course

The use of Meloxicam for the treatment of the signs and symptoms of pauciarticular or polyarticular course Juvenile Rheumatoid Arthritis in patients 2 years of age and older was evaluated in two 12-week, double-blind, parallel-arm, active-controlled trials.

Both studies included three arms: naproxen and two doses of meloxicam. In both studies, meloxicam dosing began at 0.25 mg/kg/day (0.5 mg maximum) in 0.25 mg/kg/day (15 mg maximum), and naproxen dosing began at 10 mg/kg/day. One study used these doses throughout the 12-week dosing period, while the other incorporated a titration after 4 weeks to doses of 0.25 mg/kg/day and 0.75 mg/kg/day (22.5 mg maximum) of meloxicam and 15 mg/kg/day of naproxen.

The efficacy analysis used the ACR Pediatric 30 responder definition, a composite of parent and investigator assessments, counts of active joints and joints with limited range of motion, and erythrocyte sedimentation rate. The proportion of responders were similar in all three groups in both studies, and no difference was observed between the meloxicam dose groups.

16 HOW SUPPLIED/STORAGE AND HANDLING

Meloxicam tablets USP are available as a light yellow, round, flat, uncoated tablet containing meloxicam 7.5 mg or as light yellow, oblong, biconvex, uncoated tablet containing meloxicam 15 mg. The 7.5 mg tablet is imprinted with letter U and L on one side and tablet code 7.5 on the other side. The 15 mg tablet is imprinted with letter U and L on one side and tablet code 15 on the other side.

Meloxicam Tablets USP 7.5 mg are available as follows:

NDC 70934-010-30: Bottles of 30

NDC 70934-010-60: Bottles of 60

NDC 70934-010-90: Bottles of 90

Storage/Store at 20 ° to 25 °C (68 ° to 77 °F) [see USP Controlled Room Temperature]. Keep Meloxicam tablets USP in a dry place

Dispense tablets in a tight container.

Keep this and all medications out of the reach of children.

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide) that accompanies each prescription dispensed.

Additional Medication Guides can be obtained by calling Unichem at 1-866-562-4616.

Inform patients, families or their caregivers of the following information before initiating therapy with an NSAID and periodically during the course of ongoing therapy.

Cardiovascular Thrombotic Events

Advise patients to be alert for the symptoms of cardiovascular thrombotic events, including chest pain, shortness of breath, weakness, or slurring of speech, and to report any of these symptoms to their healthcare provider immediately [see Warnings and Precautions (5.1)].

Gastrointestinal Bleeding, Ulceration, and Perforation

Advise patients to report symptoms of ulceration and bleeding, including epigastric pain, dyspepsia, nausea, and hematemesis to their healthcare provider. In the setting of concomitant use of low-dose aspirin for cardiac prophylaxis, inform patients of the increased risk for bleeding. Advise patients to report any of the signs and symptoms of GI bleeding [see Warnings and Precautions (5.2)].

Hepatotoxicity

Inform patients of the warning signs and symptoms of hepatotoxicity (e.g., nausea, fatigue, lethargy, diarrhea, pruritus, jaundice, right upper quadrant tenderness, and "flu-like" symptoms). If these occur, instruct patients to stop Meloxicam tablets and seek immediate medical therapy [see Warnings and Precautions (5.3)].

Heart Failure and Edema

Advise patients to be alert for the symptoms of congestive heart failure including shortness of breath, unexplained weight gain, or edema and to contact their healthcare provider if such symptoms occur [see Warnings and Precautions (5.3)].

Anaphylactic Reactions

Inform patients of the signs of an anaphylactic reaction (e.g., difficulty breathing, swelling of the face or throat). Inform patients to seek immediate emergency help if these occur [see Contraindications (4) and Warnings and Precautions (5.3)].

Serious Skin Reactions

Advise patients to stop Meloxicam tablets immediately if they develop any type of rash and to contact their healthcare provider as soon as possible [see Warnings and Precautions (5.9)].

Fetal Toxicity

Advise females of reproductive potential who desire pregnancy that NSAIDs, including Meloxicam tablets, may be associated with a reversible delay in ovulation [see Use in Specific Populations (8.3)].

Fetal Toxicity

Inform pregnant women to avoid use of Meloxicam tablets and other NSAIDs, starting at 30 weeks gestation because of the risk of the premature closing of the fetal ductus arteriosus [see Warnings and Precautions (5.10) and Use in Specific Populations (8.1)].

Avoid Concomitant Use of NSAIDs

Inform patients that the concomitant use of Meloxicam tablets with other NSAIDs or salicylates (e.g., effervescent tablets) is not recommended due to the increased risk of gastrointestinal toxicity, and little or no increase in efficacy [see Warnings and Precautions (5.2) and Drug Interactions (7)]. Alert patients that NSAIDs may be present in "over the counter" medications for treatment of colds, fever, or influenza.

Use of NSAIDs and Low-Dose Aspirin

Inform patients not to use low-dose aspirin concurrently with Meloxicam tablets until they talk to their healthcare provider [see Drug Interactions (7)].

For current prescribing information, call Unichem at 1-866-562-4616.

SPL MEDGUIDE

Medication Guide for Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)
What is the most important information I should know about medicines called Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)?
NSAIDs can cause serious side effects, including:
• Increased risk of a heart attack or stroke that can lead to death. This risk may happen early in treatment and may increase:
o with increasing doses of NSAIDs.
o with longer use of NSAIDs.
Do not take NSAIDs, right before or after a heart surgery called a coronary artery bypass graft (CABG).
• Avoid taking NSAIDs after a recent heart attack, unless your healthcare provider tells you to. If you have or are at risk for a heart attack, avoid taking NSAIDs after a recent heart attack.
• Increased risk of bleeding, ulcers, and tears (perforation) of the esophagus (tube leading from the mouth to the stomach), stomach and intestines.
o anytime during use
o without warning symptoms
o that may cause death
The risk of getting an ulcer or bleeding increases with:
