

other NSAIDs). Severe, sometimes fatal, anaphylactic reactions to NSAIDs have been reported in such patients [see Warnings and Precautions (5.7, 5.8)]

- In the setting of coronary artery bypass graft (CABG) surgery [see Warnings and Precautions (5.3.1)]

5 WARNINGS AND PRECAUTIONS

5.1 Cardiovascular Thrombotic Events

Clinical trials of several COX-2 selective and nonselective NSAIDs of up to three years duration have shown an increased risk of serious cardiovascular (CV) thrombotic events, including myocardial infarction (MI) and stroke, which can be fatal. Based on available data, it is unclear that the risk for CV thrombotic events is similar for all NSAIDs. The relative increase in serious CV thrombotic events over benefits conferred by NSAID use appears to be similar in those with and without known CV disease or risk factors for CV disease. However, patients with known CV disease or risk factors had a higher absolute incidence of excess serious CV thrombotic events, due to their increased baseline risk. Some observational studies found that this increased risk of serious CV thrombotic events began as early as the first weeks of treatment. The increase in CV thrombotic risk has been observed most consistently at higher doses.

To minimize the potential risk for an adverse CV event in NSAID-treated patients, use the lowest effective dose for the shortest duration possible. Physicians and patients should remain alert for the development of such events, throughout the entire treatment course, even in the absence of previous CV symptoms. Patients should be informed about the symptoms of serious CV events and the steps to take if they occur.

There is no consistent evidence that concurrent use of aspirin mitigates the increased risk of serious CV thrombotic events associated with NSAID use. The concurrent use of aspirin and an NSAID, such as meloxicam, increases the risk of serious gastrointestinal (GI) events [see Warnings and Precautions (5.2)]

Status Post Coronary Artery Bypass Graft (CABG) Surgery Two large, controlled clinical trials of a COX-2 selective NSAID for the treatment of pain in the first 10-14 days following CABG surgery found an increased incidence of myocardial infarction and stroke. NSAIDs are contraindicated in the setting of CABG [see Contraindications (4)]

Status Post MI Patients

Observational studies conducted in the Danish National Registry have demonstrated that patients treated with NSAIDs in the post-MI period were at a increased risk of myocardial CV-related death, and all-cause mortality beginning in the first week of treatment. In this analysis, the incidence of death in the first year post-MI was 20.0 percent in patients in NSAID-treated patients compared to 12 per 100 person years in non-NSAID exposed patients. Although the absolute rate of death declined somewhat after the first year post-MI, the increased relative risk of death in NSAID users persisted over at least the next four years of follow-up.

Avoid the use of meloxicam in patients with a recent MI unless the benefits are expected to outweigh the risk of recurrent CV thrombotic events. If meloxicam is used in patients with a recent MI, monitor patients for signs of cardiac ischemia.

5.2 Gastrointestinal Bleeding, Ulceration, and Perforation

NSAIDs, including meloxicam, can cause serious gastrointestinal (GI) adverse events including ulceration, bleeding, ulceration, and perforation of the esophagus, stomach, small intestine, or large intestine, which can be fatal. These serious adverse events can occur without warning symptoms, and without any prior evidence of GI lesions in patients treated with NSAIDs. Only one in five patients who develop a serious upper GI adverse event on NSAID therapy is symptomatic. Upper GI ulcers, gross bleeding, or perforation caused by NSAIDs occurred in approximately 1% of patients treated for 3-6 months, and in about 2-4% of patients treated for one year. However, even short-term NSAID therapy is not without risk.

Risk Factors for GI Bleeding, Ulceration, and Perforation

Patients with a prior history of peptic ulcer disease and/or GI bleeding who used NSAIDs had a greater than 10-fold increased risk of developing a GI bleed compared to patients without these risk factors. Other factors that increase the risk of GI bleeding in patients treated with NSAIDs include longer duration of NSAID therapy; concomitant use of oral corticosteroids, aspirin, anticoagulants, or selective serotonin reuptake inhibitors (SSRIs); smoking; use of alcohol; older age; and poor general health status. Most postmarketing reports of fatal GI events occurred in elderly or debilitated patients. Additionally, patients with advanced liver disease and/or coagulopathy are at an increased risk for GI bleeding.

Strategies to Minimize the GI Risks in NSAID-treated patients

- Use the lowest effective dosage for the shortest possible duration.
- Avoid administration of more than one NSAID at a time.
- Avoid use in patients at higher risk unless benefits are expected to outweigh the increased risk of bleeding. For such patients, as well as those with active GI bleeding, consider alternative therapies other than NSAIDs.
- Remain alert for signs and symptoms of GI ulceration and bleeding during NSAID therapy.
- If a serious GI adverse event is suspected, promptly initiate evaluation and treatment, and discontinue meloxicam until a serious GI adverse event is ruled out.
- In the setting of concomitant use of low-dose aspirin for cardiac prophylaxis, monitor patients more closely for evidence of GI bleeding [see Drug Interactions (7)]

5.3 Hepatotoxicity

Elevations of ALT or AST (three or more times the upper limit of normal [ULN]) have been reported in approximately 1% of NSAID treated patients in clinical trials. In addition, rare, sometimes fatal, cases of severe hepatic injury, including fulminant hepatitis, liver necrosis, and hepatic failure have been reported.

Elevations of ALT or AST (less than three times ULN) may occur in up to 15% of patients treated with meloxicam, including patients from patients at the warning signs and symptoms of hepatotoxicity (e.g., nausea, fatigue, lethargy, diarrhea, jaundice, anorexia, and weight loss). In most cases, these abnormalities are asymptomatic and resolve. In some cases, these abnormalities are symptomatic and may be associated with liver disease development, or if systemic manifestations occur (e.g., eosinophilia, rash, etc.), discontinue meloxicam immediately, and perform a clinical evaluation of the patient [see Use in Specific Populations (8.6) and Clinical Pharmacology (12.3)]

5.4 Hypertension

NSAIDs, including meloxicam, can lead to new onset or worsening of preexisting hypertension, either of which may contribute to the increased incidence of CV events. Patients taking antihypertensive converting enzyme (ACE) inhibitors, thiazide diuretics, or loop diuretics may have impaired response to these therapies when taking NSAIDs [see Drug Interactions (7)]

Monitor blood pressure (BP) during the initiation of NSAID treatment and throughout the course of therapy.

5.5 Heart Failure and Edema

The COX-2 and traditional NSAID Trialists' Collaboration meta-analysis of randomized controlled trials demonstrated an approximately two-fold increase in hospitalizations for heart failure in COX-2 selective-treated patients and nonselective NSAID-treated patients compared to placebo-treated patients. In a Danish National Registry study of patients with heart failure, NSAID use increased the risk of MI, hospitalization for heart failure, and death. Additionally, fluid retention and edema have been observed in some patients treated with NSAIDs. Use of meloxicam may cause fluid retention, and the effects of several other agents used to treat these medical conditions (e.g., diuretics, ACE inhibitors, or angiotensin receptor blockers [ARBs]) [see Drug Interactions (7)]

Avoid the use of meloxicam in patients with severe heart failure unless the benefits are expected to outweigh the risk of worsening heart failure. If meloxicam is used in patients with severe heart failure, monitor patients for signs of worsening heart failure.

5.6 Renal Toxicity and Hyperkalemia

Renal Toxicity

Long-term administration of NSAIDs, including meloxicam, has resulted in renal papillary necrosis, renal insufficiency, acute renal failure, and other renal injury. Renal toxicity has also been seen in patients in whom renal prostaglandin formation is a compensatory route in the maintenance of renal perfusion. In these patients, administration of an NSAID may cause a dose-dependent reduction in prostaglandin formation and, secondarily, in renal blood flow, which may precipitate overt renal decompensation. Patients at greatest risk of this reaction are those with impaired renal function, dehydration, hypovolemia, heart failure, liver dysfunction, those taking diuretics and ACE inhibitors or ARBs, and the elderly. Avoidance of NSAID therapy is usually followed by recovery to the pre-treatment state.

The renal effects of meloxicam may hasten the progression of renal dysfunction in patients with preexisting renal disease. Because some meloxicam metabolites are secreted by the kidney, meloxicam may be contraindicated in patients with a significant volume status in dehydrated or hypovolemic patients prior to initiating meloxicam. Monitor for evidence of renal impairment in patients receiving meloxicam heart failure, dehydration, or hypovolemia during use of meloxicam [see Drug Interactions (7)]

Information is available from controlled clinical studies regarding the use of meloxicam in patients with advanced renal disease. Avoid the use of meloxicam in patients with advanced renal disease unless the benefits are expected to outweigh the risk of worsening renal function. If meloxicam is used in patients with advanced renal disease, monitor patients for signs of worsening renal function [see Clinical Pharmacology (12.3)]

Hypokalemia

Increases in serum potassium concentration, including hyperkalemia, have been reported with use of NSAIDs, even in some patients without renal impairment. In patients with normal renal function, these effects have been attributed to a "pseudohypoaldosteronism" state.

5.7 Anaphylactic Reactions

Meloxicam has been associated with anaphylactic reactions in patients with and without known hypersensitivity to meloxicam and in patients with aspirin-sensitive asthma [see Contraindications (4) and Warnings and Precautions (5.8)]

Seek emergency help if an anaphylactic reaction occurs.

5.8 Exacerbation of Asthma Related to Aspirin Sensitivity

A subpopulation of patients with asthma may have aspirin-sensitive asthma which may include chronic rhinosinusitis complicated by nasal polyps, severe, potentially fatal bronchospasm, and/or intolerance to aspirin and other NSAIDs. Because cross-reactivity between aspirin and other NSAIDs has been reported in such aspirin-sensitive patients, meloxicam is contraindicated in patients with this form of aspirin sensitivity [see Contraindications (4)]. When meloxicam is used in patients with preexisting asthma (without known aspirin sensitivity), monitor patients for changes in the signs and symptoms of asthma.

5.9 Serious Skin Reactions

NSAIDs, including meloxicam, can cause serious skin adverse reactions such as exfoliative dermatitis, Stevens-Johnson Syndrome (SJS), and toxic epidermal necrolysis (TEN), which can be fatal. These serious events may occur without warning. Inform patients about the signs and symptoms of serious skin reactions, and to discontinue the use of meloxicam at the first appearance of skin rash or any other sign of hypersensitivity. Meloxicam is contraindicated in patients with previous serious skin reactions to NSAIDs [see Contraindications (4)]

5.10 Premature Closure of Fetal Ductus Arteriosus

Meloxicam may cause premature closure of the fetal ductus arteriosus. Avoid use of NSAIDs, including meloxicam, in pregnant women starting at 30 weeks of gestation (third trimester) [see Use in Specific Populations (8.2)]

5.11 Hematologic Toxicity

Anemia has occurred in NSAID-treated patients. This may be due to occult or gross blood loss, fluid retention, or an increasingly described effect on erythropoiesis. If a patient treated with meloxicam has any signs or symptoms of anemia, monitor hemoglobin or hematocrit.

NSAIDs, including meloxicam, may increase the risk of bleeding events. Co-morbid conditions, such as coagulation disorders, or concomitant use of warfarin, aspirin, anticoagulants, antiplatelet agents (e.g., aspirin), serotonin reuptake inhibitors (SSRIs) and serotonin reuptake inhibitors (SRIs), may increase this risk. Monitor these patients for signs of bleeding [see Drug Interactions (7)]

5.12 Masking of Inflammation and Fever

The pharmacological activity of meloxicam is masking inflammation, and possibly fever, may diminish the utility of diagnostic signs in detecting infections.

5.13 Laboratory Monitoring

Because serious GI bleeding, hepatotoxicity, and renal injury can occur without warning symptoms or signs, consider monitoring patients on long-term NSAID treatment with a CBC and a chemistry profile periodically [see Warnings and Precautions (5.2, 5.3, 5.8)]

6 ADVERSE REACTIONS

The following adverse reactions are discussed in greater detail in other sections of the labeling:

- Cardiovascular Thrombotic Events [see Boxed Warning and Warnings and Precautions (5.1)]
- GI Bleeding, Ulceration, and Perforation [see Boxed Warning and Warnings and Precautions (5.2)]
- Hepatotoxicity [see Warnings and Precautions (5.3)]
- Hypertension [see Warnings and Precautions (5.4)]
- Heart Failure and Edema [see Warnings and Precautions (5.5)]
- Renal Toxicity and Hyperkalemia [see Warnings and Precautions (5.6)]
- Anaphylactic Reactions [see Warnings and Precautions (5.7)]
- Serious Skin Reactions [see Warnings and Precautions (5.9)]
- Hematologic Toxicity [see Warnings and Precautions (5.11)]

6.1 Clinical Trial Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice.

Adults

Osteoarthritis and Rheumatoid Arthritis

The meloxicam Phase 2/3 clinical trial database includes 16,122 OA patients and 1012 RA patients treated with meloxicam 7.5 mg daily, 355 OA patients and 133 RA patients treated with meloxicam 15 mg daily, and 189 OA patients and 133 RA patients treated with placebo for at least 6 months and to 312 patients for at least one year. Approximately 15,293 of these patients were treated in the placebo- and/or active-controlled trials and 2383 of these patients were treated in two placebo- and/or active-controlled rheumatoid arthritis trials. Gastrointestinal (GI) adverse events were the most frequently reported adverse events in all treatment groups across meloxicam trials.

A 12-week meloxicam double-blind, controlled trial was conducted in patients with osteoarthritis of the knee or hip to compare the efficacy and safety of meloxicam with placebo and with an active control. Two 12-week meloxicam double-blind, randomized trials were conducted in patients with rheumatoid arthritis to compare the efficacy and safety of meloxicam with placebo.

Table 1a depicts adverse events that occurred in ≥2% of the meloxicam treatment groups in a 12-week placebo- and active-controlled osteoarthritis trial.

Table 1a depicts adverse events that occurred in ≥2% of the meloxicam treatment groups in two 12-week placebo-controlled rheumatoid arthritis trials.

Table 1a Adverse Events (%) Occurring in ≥ 2% of Meloxicam Patients in a 12-Week Osteoarthritis Placebo- and Active-Controlled Trial				
	Placebo	Meloxicam 7.5 mg daily	Meloxicam 15 mg daily	Placebo/active 100 mg daily
No. of Patients	139	355	185	183
Gastrointestinal	12.9	20.3	17.3	18.1
	1.9	2.5	2.5	3.3

Data

Animal Data
Mefenamic acid was not teratogenic when administered to pregnant rats during fetal organogenesis at oral doses up to 4 mg/kg/day (2.6-fold greater than the MWHO of 15 mg of mefenamic acid based on BSA comparison). Administration of mefenamic acid to pregnant rabbits throughout embryogenesis produced an increased incidence of skeletal defects of the heart at an oral dose of 60 mg/kg/day (10-fold greater than the MWHO based on BSA comparison). The no effect level was 20 mg/kg/day (16-fold greater than the MWHO based on BSA comparison). In rats and rabbits, embryotoxicity occurred at oral mefenamic doses of 1 mg/kg/day and 8 mg/kg/day, respectively (ESD and 5-fold greater, respectively, than the MWHO based on BSA comparison) when administered throughout organogenesis.

Oral administration of mefenamic to pregnant rats during late gestation through lactation increased the incidence of dystocia, delayed parturition, and decreased offspring survival at mefenamic doses of 1.125 mg/kg/day or greater (0.08 times MWHO based on BSA comparison).

8.1 Lactation

Risk Summary

There are no human data available on whether mefenamic is present in human milk, or on the effects on breastfed infants, or on milk production. The developmental and health benefits of breastfeeding should be considered along with the mother's clinical need for mefenamic and any potential adverse effects on the breastfed infant from the mefenamic or from the underlying maternal condition.

Data

Animal data
Mefenamic was present in the milk of lactating rats at concentrations higher than those in plasma.

8.3 Females and Males of Reproductive Potential

Infertility Females

Based on the mechanism of action, the use of prostaglandin-mediated NSAIDs, including mefenamic, may delay or prevent rupture of ovarian follicles, which has been associated with reversible infertility in some women. Published animal studies have shown that administration of prostaglandin synthesis inhibitors has the potential to disrupt prostaglandin-mediated follicular rupture required for ovulation. Clinical studies in women treated with NSAIDs have also shown a reversible delay in ovulation. Consider withdrawal of NSAIDs, including mefenamic, in women who have difficulties conceiving or who are undergoing investigation of infertility.

8.4 Pediatric Use

The safety and effectiveness of mefenamic in pediatric (JA) patients from 2 to 17 years of age has been evaluated in three clinical trials [see Dosage and Administration (2.3), Adverse Reactions (6.1) and Clinical Studies (14.2)].

8.5 Geriatric Use

Elderly patients, compared to younger patients, are at greater risk for NSAID associated adverse cardiovascular, gastrointestinal, and/or renal adverse reactions. If the anticipated benefit for the elderly patient outweighs these potential risks, start dosing at the low end of the dosing range and monitor patients for adverse effects [see Warnings and Precautions (5.2, 5.3, 5.5, 5.6, 5.10)].

8.6 Hepatic Impairment

No dose adjustment is necessary in patients with mild to moderate hepatic impairment. Patients with severe hepatic impairment have not been adequately studied. Since mefenamic is significantly metabolized in the liver and hepatotoxicity may occur, use mefenamic with caution in patients with hepatic impairment [see Warnings and Precautions (5.3) and Clinical Pharmacology (12.3)].

8.7 Renal Impairment

No dose adjustment is necessary in patients with mild to moderate renal impairment. Patients with severe renal impairment have not been studied. The use of mefenamic in subjects with severe renal impairment is not recommended. In patients on hemodialysis, mefenamic should not exceed 7.5 mg per day. Mefenamic is not dialyzable [see Dosage and Administration (2.2) and Clinical Pharmacology (12.3)].

10 OVERDOSE

Symptoms following acute NSAID overdosages have been typically limited to lethargy, drowsiness, nausea, vomiting, and epigastric pain, which have been generally reversible with supportive care. Gastrointestinal bleeding has occurred. Hypertension, acute renal failure, respiratory depression, and coma have occurred, but were rare [see Warnings and Precautions (5.2, 5.2, 5.4, 5.6)].

Manage patients with symptomatic and supportive care following an NSAID overdose. There are no specific antidotes. Consider emesis and/or activated charcoal (0.5 to 100 grams in adults, 1 to 2 grams per kg of body weight in pediatric patients) and/or gastric catheter in symptomatic patients seen within four hours of ingestion or in patients with a proven overdose 5 to 6 times the recommended dosage. For patients with dyspnea, alkalization of urine, hemodialysis, or hemoperfusion may not be useful due to high protein binding.

There is limited experience with mefenamic overdose. Cholestyramine is known to accelerate the clearance of mefenamic. Accelerated removal of mefenamic by 4 g oral doses of cholestyramine given three times a day was demonstrated in a clinical trial. Administration of cholestyramine may be useful following an overdose. For additional information about overdose treatment, call a poison control center (1-800-222-1222).

11 DESCRIPTION

Mefenamic is a nonsteroidal anti-inflammatory drug (NSAID). Each yellow mefenamic tablet contains 7.5 mg or 15 mg mefenamic for oral administration. Mefenamic is chemically equivalent to 4-(4-chlorophenyl)-2-methyl-5-(2-methylphenyl)-3-pyrazolecarboxamide; 3-carboxamide-1,1-dioxide. The molecular weight is 351.4. Its empirical formula is $C_{17}H_{14}ClN_2O_3$ and it has the following structural formula:

Mefenamic, USP is a pale yellow powder, practically insoluble in water, slightly soluble in acetone, soluble in dimethylformamide, very slightly soluble in ethanol (5% to and in methanol. Mefenamic has an apparent partition coefficient log P of -5.1 in octanol versus water. The apparent partition coefficient of log P is -5.1 in octanol versus water. Each mefenamic tablet, USP intended for oral administration contains 7.5 mg or 15 mg mefenamic. In addition, each tablet contains the following inactive ingredients: cobalt(II) chloride, croscarmellose, lactose monohydrate, magnesium stearate, microcrystalline cellulose, polyvinyl and sodium citrate dihydrate.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

Mefenamic has prostaglandin, anti-inflammatory, and antipyretic properties. The mechanism of action of mefenamic, like that of other NSAIDs, is not completely understood but involves inhibition of cyclooxygenase (COX-1 and COX-2). Mefenamic is a potent inhibitor of prostaglandin synthesis *in vitro*. Mefenamic concentrations reached during therapy have produced *in vivo* effects. Prostaglandins sensitize afferent nerves and potentiate the action of bradykinin in inducing pain in animal models. Prostaglandins are mediators of inflammation. Because mefenamic is an inhibitor of prostaglandin synthesis, its mode of action may be due to a decrease in prostaglandin synthesis.

12.3 Pharmacokinetics

Absorption

The absolute bioavailability of mefenamic capsule was 89% following a single oral dose of 30 mg compared with 30 mg IV bolus injection. Following single intravenous doses, dose-proportional pharmacokinetics were shown in the range of 5 mg to 60 mg. After multiple oral doses the pharmacokinetics of mefenamic capsules were dose-proportional over the range of 7.5 mg to 15 mg. Mean C_{max} was achieved within four to five hours after a 7.5 mg mefenamic tablet was taken under fasting conditions, indicating a rapid gastric emptying rate. Mean C_{max} was reached after steady-state conditions were reached by Day 5. A second mefenamic concentration peak occurs around 12 to 14 hours post-dose suggesting biliary recirculation. Mefenamic oral suspension doses of 7.5 mg/5 mL and 15 mg/10 mL have been found to be bioequivalent to mefenamic 7.5 mg and 15 mg tablets, respectively. Mefenamic capsules have been shown to be bioequivalent to mefenamic tablets.

Table 4:Single Dose and Steady-State Pharmacokinetic Parameters for Oral 7.5 mg and 15 mg Mefenamic (Mean and % CV) ¹

Pharmacokinetic Parameters (n=10)	Steady State			Single Dose		
	Healthy male adults (Fed) ^a		Elderly males (Fed) ^a	Elderly females (Fed) ^a	Renal failure (Fasted)	Hepatic insufficiency (Fasted)
	7.5 mg tablets	15 mg capsules	15 mg capsules	15 mg capsules	15 mg capsules	15 mg capsules
	N	18	5	5	12	12
C _{max} (mg/L)	1.05 (24)	2.1 (39)	3.2 (44)	0.33 (18)	0.84 (12)	
t _{1/2} (h)	4.9 (8)	3.1 (12)	3.7 (12)	1.9 (6)	10 (7)	
AUC (mg·h/L)	20.1 (29)	21.1 (34)	21.1 (34)	18 (14)	16 (14)	
CL _R (mL/min)	2.8 (29)	3.9 (16)	5.5 (22)	19 (43)	11 (29)	
t _{1/2} (h)	14 (21)	15 (12)	10 (10)	26 (14)	14 (20)	

¹See package insert for the full text of the clinical studies.
²See package insert for the full text of the clinical studies.

Food and Antacid Effects

Administration of mefenamic capsule following a high fat breakfast (75 g of fat) resulted in a mean peak drug level in plasma that was approximately 27% higher than the extent of absorption (AUC) was unchanged. The time to maximum concentration (T_{max}) was unchanged between 2 and 6 hours. In comparison, neither the AUC nor the C_{max} values for mefenamic suspension were affected following a similar high fat meal, while mean T_{max} values were increased to approximately 7 hours. No pharmacokinetic interaction was detected with concomitant administration of antacids. Based on these results, mefenamic can be administered without regard to timing of meals or concomitant administration of antacids.

Distribution
The mean volume of distribution (V_d) of mefenamic is approximately 10 L. Mefenamic is 94% bound to human plasma proteins primarily albumin when the therapeutic dose range. The fraction of protein binding is independent of drug concentration, over the clinically relevant concentration range, but decreases to ~88% in patients with renal disease. Mefenamic penetration into human red blood cells, after oral dosing, is less than 10%. Following a radiolabeled dose, over 90% of the radioactivity detected in the plasma was present as unchanged mefenamic.

Mefenamic concentrations in synovial fluid, after a single oral dose, range from 40% to 50% of those in plasma. The free fraction in synovial fluid is 2.5 times higher than in plasma, due to the lower albumin content in synovial fluid as compared to plasma. The significance of this penetration is unknown.

Elimination

Metabolism

Mefenamic is extensively metabolized in the liver. Mefenamic metabolites include 5'-carboxy mefenamic (50% of dose), from P450 mediated metabolism formed by oxidation of an intermediate metabolite 5'-hydroxymethyl mefenamic which is also excreted to a lesser extent (5% of dose). *In vitro* studies indicate that CYP2C9 (cytochrome P450 metabolizing enzyme) plays an important role in this metabolic pathway with a minor contribution of the CYP2C8 enzyme. Patient's genotypic activity is probably responsible for the lower two metabolites which account for 14% and 4% of the administered dose, respectively. At the four metabolites, are not known to have any pharmacological activity.

Excretion

Mefenamic excretion is predominantly in the form of metabolites, and occurs to equal extents in the urine and feces. Only traces of the unchanged parent compound are excreted in the urine (0.2%) and feces (1.4%). The extent of the urinary excretion was confirmed for unlabeled mefenamic 7.5 mg doses (3.5%, 4.5%, and 1.5% of the dose were found in urine in the form of mefenamic and the 5'-hydroxymethyl and 5'-carboxy metabolites, respectively. There is significant biliary and/or enteric excretion of the drug. The data demonstrated when the administration of radiolabeled mefenamic following a single IV dose of mefenamic decreased the AUC of mefenamic by 50%.

The mean elimination half-life (t_{1/2}) ranges from 15 hours to 20 hours. The elimination half-life is constant across dose levels including lower metabolites within the therapeutic dose range. Plasma clearance ranges from 7 to 9 mL/min.

Specific Populations

Pediatric After single (0.25 mg/kg) dose administration and after achieving steady state (0.25 mg/kg/day), there was a general trend of approximately 20% higher plasma concentrations in younger patients (2 to 6 years old) as compared to the older patients (7 to 16 years old). The older patients had mefenamic exposures similar (single dose) or slightly reduced (steady state) to those in the adult patients, when using AUC values normalized to a dose of 0.25 mg/kg [see Dosage and Administration (2.4)]. The mefenamic mean (SD) elimination half-life was 15.2 (1.0) and 13.0 (3.0) for the 2 to 6 year old patients, and 7 to 16 year old patients, respectively.

In a covariate analysis, utilizing population pharmacokinetics, body weight, but not age, was the single predictor covariate for differences in the mefenamic apparent oral plasma clearance. The body-weight normalized apparent oral clearance values were adequate predictors of mefenamic exposure in pediatric patients.

The pharmacokinetics of mefenamic in pediatric patients under 2 years of age have not been investigated.

Geriatric

Elderly males (≥ 65 years of age) exhibited mefenamic plasma concentrations and steady-state pharmacokinetics similar to young males. Elderly females (≥ 65 years of age) had a 4% higher AUCs and 32% higher C_{max} as compared to younger females. In 55 years of age after body weight normalization, despite the increased total plasma concentrations in the elderly females, the adverse effect profile was comparable to the elderly patient populations. A smaller free fraction was found in elderly female patients in comparison to elderly male patients.

Sex

Young females exhibited slightly lower plasma concentrations relative to young males. After single doses of 7.5 mg mefenamic, the mean elimination half-life was 18.5 hours for the female group as compared to 23.4 hours for the male group. At steady state, the data were similar (17.7 hours vs 21.4 hours). The pharmacokinetic differences due to gender is likely to be of little clinical importance. There was no effect of pharmacokinetics and/or appreciable difference in the C_{max} or T_{max} across genders.

Hepatic Impairment

Following a single 15 mg dose of mefenamic there was no marked difference in plasma concentrations in patients with mild (Child-Pugh Class I) or moderate (Child-Pugh Class II) hepatic impairment compared to healthy volunteers. Protein binding of mefenamic was not affected by hepatic impairment. No dosage adjustment is necessary in patients with mild to moderate hepatic impairment. Patients with severe hepatic impairment

(C248) Porph. Class. III) have not been adequately studied | see Warnings and Precautions (5.3) and Use in Specific Populations (8.6)

Renal Impairment

Meloxicam pharmacokinetics have been investigated in subjects with mild and moderate renal impairment. Total drug plasma concentrations of meloxicam decreased and total clearance of meloxicam increased with the degree of renal impairment while free AUC values were similar in all groups. The higher meloxicam clearance in subjects with renal impairment may be due to increased fraction of unbound meloxicam which is available for metabolism and subsequent excretion. No dosage adjustment is necessary in patients with mild to moderate renal impairment. Patients with severe renal impairment have not been adequately studied. The use of meloxicam in subjects with severe renal impairment is not recommended | see Dosage and Administration (2.5), Warnings and Precautions (5.6) and Use in Specific Populations (8.7) |

Hemodialysis

Following a single dose of meloxicam, the free C_{max} plasma concentrations were higher in patients with renal failure on chronic hemodialysis (5% free fraction) in comparison to healthy volunteers (0.3% free fraction). Hemodialysis did not lower the total drug concentration in plasma. Therefore, additional doses are not necessary after hemodialysis. Meloxicam is not dialyzable | see Dosage and Administration (2.1), and Use in Specific Populations (8.7)

Drug Interaction Studies

Aspirin

When NSAIDs were administered with aspirin, the protein binding of NSAIDs were reduced, although the clearance of free NSAID was not altered. When meloxicam is administered with aspirin (1000 mg three times daily) to healthy volunteers, it tended to increase the AUC (0.6) and C_{max} (4.6%) of meloxicam. The clinical significance of this interaction is not known. See Table 3 for clinically significant drug interactions of NSAIDs with aspirin | see Drug Interactions (7)

Cholestyramine

Pre-treatment for four days with cholestyramine significantly increased the clearance of meloxicam by 50%. This resulted in a decrease in t_{1/2} from 19.2 hours to 12.5 hours, and a 35% reduction in AUC. This suggests the existence of a recirculation pathway for meloxicam in the gastrointestinal tract. The clinical relevance of this interaction has not been established.

Cimetidine

Concomitant administration of 200 mg cimetidine four times daily did not alter the single-dose pharmacokinetics of 30 mg meloxicam.

Digoxin

Meloxicam 15 mg once daily for 7 days did not alter the plasma concentration profile of digoxin after 8-metoprolol administration for 7 days at clinical doses. In vitro testing found no protein binding drug interaction between digoxin and meloxicam.

Lithium

In a study conducted in healthy subjects, mean pre-dose lithium concentrations and AUC were increased by 25% in subjects receiving lithium doses ranging from 600 to 3072 mg twice daily with meloxicam 15 mg QD every day as compared to subjects receiving lithium alone | see Drug Interactions (7)

Methotrexate

A study in 13 rheumatoid arthritis (RA) patients evaluated the effects of multiple doses of meloxicam on the pharmacokinetics of methotrexate taken once weekly. Meloxicam did not have a significant effect on the pharmacokinetics of single doses of methotrexate. In vitro, methotrexate did not displace meloxicam from its human serum binding sites | see Drug Interactions (7)

Warfarin

The effect of meloxicam on the anticoagulant effect of warfarin was studied in a group of healthy subjects receiving daily doses of warfarin that produced an INR (International Normalized Ratio) between 1.2 and 1.8. In these subjects, meloxicam did not alter warfarin pharmacokinetics and the average anticoagulant effect of warfarin, as measured by prothrombin time. However, one subject had an increase in INR from 1.5 to 2.1. Caution should be used when administering meloxicam with warfarin since patients on warfarin may experience changes in INR and an increased risk of bleeding complications when a new medication is introduced | see Drug Interactions (7)

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Carcinogenesis

There was no increase in tumor incidence in long-term carcinogenicity studies in rats (24 weeks) and mice (99 weeks) administered meloxicam at oral doses up to 0.8 mg/kg/day in rats and up to 0.8 mg/kg/day in mice (at 0.5 and 2.6 times, respectively, the maximum recommended human dose [MRHD] of 15 mg/day meloxicam based on body surface area [BSA] comparison).

Mutagenesis

Meloxicam was not mutagenic in an Ames assay, or clastogenic in a chromosome aberration assay with human lymphocytes and an in vivo micronucleus test in mouse bone marrow.

Impairment of Fertility

Meloxicam did not impair male and female fertility in rats at oral doses up to 9 mg/kg/day in males and 1 mg/kg/day in females (up to 5.8- and 3.2-times greater, respectively, than the MRHD based on BSA comparison).

14 CLINICAL STUDIES

14.1 Osteoarthritis and Rheumatoid Arthritis

The use of meloxicam for the treatment of the signs and symptoms of osteoarthritis of the knee and hip was evaluated in a 12-week, double-blind, controlled trial: meloxicam (7.5 mg, 15 mg, and 15 mg daily) was compared to placebo. The four primary endpoints were investigator's global assessment, patient global assessment, patient pain assessment, and total WOMAC score in self-administered questionnaire addressing pain, function, and stiffness. Patients on meloxicam 7.5 mg daily and meloxicam 15 mg daily showed significant improvement in each of these endpoints compared with placebo.

The use of meloxicam for the management of signs and symptoms of rheumatoid arthritis was evaluated in a double-blind, active-controlled trial outside the U.S., ranging from 4 weeks to 16 weeks' duration. In these trials, the efficacy of meloxicam in doses of 7.5 mg/day and 15 mg/day was comparable to placebo 20 mg/day and diclofenac 50-100 mg/day and consistent with the efficacy seen in the U.S. trial.

The use of meloxicam for the treatment of the signs and symptoms of rheumatoid arthritis was evaluated in a 12-week, double-blind, controlled multinational trial: meloxicam (7.5 mg, 15 mg, and 22.5 mg daily) was compared to placebo. The primary endpoint in this study was the ACR20 response rate, a composite measure of clinical, functional, and functional measures of response. Patients receiving placebo, 7.5 mg and 15 mg showed significant improvement in the primary endpoint compared with placebo. No incremental benefit was observed with the 22.5 mg dose compared to the 15 mg dose.

14.2 Juvenile Rheumatoid Arthritis (JRA) Pauciarticular and Polyarticular Course

The use of meloxicam for the treatment of the signs and symptoms of pauciarticular or polyarticular course juvenile rheumatoid arthritis in patients 2 years of age and older was evaluated in two 12-week, double-blind, parallel-arm, active-controlled trials.

Both studies included three arms: naproxen and two doses of meloxicam. In both studies, meloxicam dosing began at 0.125 mg/kg/day (7.5 mg maximum) or 0.25 mg/kg/day (15 mg maximum), and naproxen dosing began at 10 mg/kg/day. One study used these doses throughout the 12-week dosing period, while the other incorporated a titration after 4 weeks to doses of 0.25 mg/kg/day and 0.375 mg/kg/day (22.5 mg maximum) of meloxicam and 15 mg/kg/day of naproxen.

The efficacy analysis used the ACR Pediatric 20 responder definition, a composite of parent and investigator assessments, counts of active joints and joints with limited range of motion, and erythrocyte sedimentation rate. The proportion of responders were similar in all three groups in both studies, and no difference was observed between the meloxicam dose groups.

16 HOW SUPPLIED/STORAGE AND HANDLING

Meloxicam Tablets USP, 15 mg are yellow, round-shaped, flat beveled edges, unincised tablet debossed with ZC and 26 on one side and plain on other side and are supplied as follows:

NDC 68071-3030-7 BOTTLES OF 7

NDC 68071-3030-5 BOTTLES OF 15

NDC 68071-3030-9 BOTTLES OF 90

Storage

Store at 20° to 25° C (68° to 77° F) [see USP Controlled Room Temperature]. Keep meloxicam tablets in a dry place.

Dispense tablets in a tight container.

Keep this and all medications out of the reach of children.

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide) that accompanies each prescription dispensed.

Inform patients, families or their caregivers of the following information before initiating therapy with an NSAID and periodically during the course of ongoing therapy.

Cardiovascular Thrombotic Events

Advise patients to be alert for the symptoms of cardiovascular thrombotic events, including chest pain, shortness of breath, weakness, or slurring of speech, and to report any of these symptoms to their healthcare provider immediately | see Warnings and Precautions (5.1) |

Gastrointestinal Bleeding, Ulceration, and Perforation

Advise patients to report symptoms of ulcerations and bleeding, including epigastric pain, dyspepsia, melena, and hematemesis to their healthcare provider. In the setting of concomitant use of low-dose aspirin for cardiac prophylaxis, inform patients of the increased risk for the signs and symptoms of GI bleeding | see Warnings and Precautions (5.2) |

Hepatotoxicity

Inform patients of the warning signs and symptoms of hepatotoxicity (e.g., nausea, fatigue, lethargy, diarrhea, pruritus, jaundice, right upper quadrant tenderness, and "flu-like" symptoms). If these occur, instruct patients to stop meloxicam and seek immediate medical therapy | see Warnings and Precautions (5.3) |

Heart Failure and Edema

Advise patients to be alert for the symptoms of congestive heart failure including: shortness of breath, unexplained weight gain, or edema and to contact their healthcare provider if such symptoms occur | see Warnings and Precautions (5.3) |

Anaphylactic Reactions

Inform patients of the signs of an anaphylactic reaction (e.g., difficulty breathing, swelling of the face or throat). Instruct patients to seek immediate emergency help if these occur | see Contraindications (4) and Warnings and Precautions (5.3) |

Serious Skin Reactions

Advise patients to stop meloxicam immediately if they develop any form of rash and to contact their healthcare provider as soon as possible | see Warnings and Precautions (5.9) |

Female Fertility

Advise females of reproductive potential who desire pregnancy that NSAIDs, including meloxicam, may be associated with a reversible delay in ovulation | see Use in Specific Populations (8.3) |

Fetal Toxicity

Inform pregnant women to avoid use of meloxicam and other NSAIDs starting at 30 weeks gestation because of the risk of the premature closure of the fetal ductus arteriosus | see Warnings and Precautions (5.10) and Use in Specific Populations (8.4) |

Avoid Concomitant Use of NSAIDs

Inform patients that the concomitant use of meloxicam with other NSAIDs or salicylates (e.g., effervescent, sublingual) is not recommended due to the increased risk of gastrointestinal toxicity, and 80% or no increase in efficacy | see Warnings and Precautions (5.12) and Drug Interactions (7) | Advise patients that NSAIDs may be present in "over the counter" medications for treatment of colds, fever, or insomnia.

Use of NSAIDs and Low-Dose Aspirin

Inform patients not to use low-dose aspirin concomitantly with meloxicam until they talk to their healthcare provider | see Drug Interactions (7) |

Medication Guide for Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

What is the most important information I should know about medicines called Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)?

NSAIDs can cause serious side effects, including:

- **Increased risk of a heart attack or stroke that can lead to death.** This risk may happen early in treatment and may increase
 - with increasing doses of NSAIDs
 - with longer use of NSAIDs

Do not take NSAIDs right before or after a heart surgery called a "coronary artery bypass graft (CABG)."

Avoid taking NSAIDs after a recent heart attack, unless your healthcare provider tells you to. You may have an increased risk of another heart attack if you take NSAIDs after a recent heart attack.

Increased risk of bleeding, ulcers, and tears (perforation) of the esophagus (hole leading from the mouth to the stomach), stomach and intestines:

- anytime during use
- without warning symptoms
- that may cause death

The risk of getting an ulcer or bleeding increases with:

- past history of stomach ulcers, or stomach or intestinal bleeding with use of NSAIDs
