FIORINAL WITH CODEINE- butalbital, aspirin, caffeine, and codeine phosphate capsule
Actavis Pharma, Inc.

HIGHLIGHTS OF PRESCRIBING INFORMATION
These highlights do not include all the information needed to use FIORINAL with CODEINE safely and effectively. See full prescribing information for FIORINAL with CODEINE.

FIORINAL® with CODEINE (butalbital, aspirin, caffeine, and codeine phosphate, USP) capsules, for oral use, CII
Initial U.S. Approval: 1950

WARNING: ADDICTION, ABUSE, AND MISUSE; LIFE-THREATENING RESPIRATORY DEPRESSION; ACCIDENTAL INGESTION; RISK OF SERIOUS, LIFE-THREATENING RESPIRATORY DEPRESSION FROM CONCURRENT USE WITH BZDIZEPINES OR OTHER CNS DEPRESSANTS; ULTRA-RAPID METABOLISM OF CODEINE AND OTHER FACTORS FOR LIFE-THREATENING RESPIRATORY DEPRESSION IN CHILDREN; NEONATAL OPIOID WITHDRAWAL SYNDROME; AND INTERACTIONS WITH DRUGS AFFECTING CYTOCHROMES P450 ISOENZYME SYSTEMS
See full prescribing information for complete boxed warning.

- FIORINAL with CODEINE exposes users to the risks of addiction, abuse, and misuse, which can lead to overdose and death. Assess patient’s risk before prescribing and monitor regularly for these behaviors and conditions. (5.1)
- Serious, life-threatening, or fatal respiratory depression may occur. Monitor closely, especially upon initiation or following a dose increase. (5.2)
- Accidental ingestion of FIORINAL with CODEINE, especially by children, can result in fatal overdose. (5.2)
- Concomitant use of opioids or a barbiturate with benzodiazepines or other central nervous system (CNS) depressants, including alcohol, may result in profound sedation, respiratory depression, coma, and death. Reserve concomitant prescribing for use in patients for whom alternative treatment options are inadequate; limit dosages and durations to the minimum required; and follow patients for signs and symptoms of respiratory depression and sedation. (5.3)
- Life-threatening respiratory depression and death have occurred in children who received codeine; most cases followed tonsillectomy and/or adenoidectomy, and many of the children had evidence of being an ultra-rapid metabolizer of codeine due to a CYP2D6 polymorphism. (5.4) FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy. (5.4) Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.
- Prolonged use during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated. If prolonged opioid use is required in a pregnant woman, advise the patient of the risk of neonatal opioid withdrawal syndrome and ensure that appropriate treatment will be available for early identification and treatment of respiratory depression. (5.5)
- The effects of concomitant use or discontinuation of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with FIORINAL with CODEINE requires careful consideration of the effects on codeine, and the active metabolite, morphine. (5.6, 7)

Boxed Warning 08/2017
Indication and Usage (1) 12/2016
Contraindications (4) 06/2017
Warnings and Precautions (5) 08/2017

INDICATIONS AND USAGE
FIORINAL with CODEINE is a combination of butalbital, a barbiturate, aspirin, a nonsteroidal anti-inflammatory drug, caffeine, a methylxanthine, and codeine phosphate, an opioid agonist, and is indicated for the management of the symptom complex of tension (or muscle contraction) headache, when other non-opioid analgesics and alternative treatments are inadequate.

Dosage Form and Strengths
Capsules: 50 mg butalbital, 325 mg aspirin, 40 mg caffeine, and 30 mg codeine phosphate (3)

CONTRAINDICATIONS
- Children younger than 12 years of age (4)
- Post-operative management in children younger than 18 years of age following tonsillectomy and/or adenoidectomy (4)
- Significant respiratory depression (4)
- Acute or severe bronchial asthma (4)
- Concurrent use of monoamine oxidase inhibitors (MAOIs) or use of MAOIs within the last 14 days (4)
- Known or suspected gastrointestinal obstruction, including paralytic ileus (4)
- Hemorrhage, or risk factors for hemorrhage (4)
- Hemophiliacs (4)
- Reye’s Syndrome (4)
- Known allergy to NSAIDS (4)
- Syndrome of asthma, rhinitis, and nasal polyps (4)

WARNINGS AND PRECAUTIONS
- Life-Threatening Respiratory Depression in Patients with Chronic Pulmonary Disease or in Elderly, Cachectic, or Debilitated Patients: Monitor closely, particularly during initiation and titration. (5.7)
- Adrenal Insufficiency: If diagnosed, treat with physiologic replacement of corticosteroids, and wean patient off the opioid. (5.8)
- Severe Hypotension: Monitor during dose initiation and titration. Avoid use of FIORINAL with CODEINE in patients with circulatory shock. (5.10)
- Risks of Use in Patients with Increased Intracranial Pressure, Brain Tumors, Head Injury, or Impaired Consciousness: Monitor for sedation and respiratory depression. Avoid use of FIORINAL with CODEINE in patients with impaired consciousness or coma. (5.11)

Most common adverse reactions (incidence > 1%) are nausea and/or abdominal pain, drowsiness, and dizziness. (6)

**INDICATIONS AND USAGE**

FIORINAL with CODEINE is indicated for the management of the symptom complex of tension (or muscle contraction) headache, when non-opioid analgesic and alternative treatments are inadequate.

**Limitations of Use**

Because of the risks of addiction, abuse, and misuse with opioids and butalbital, even at recommended doses [see Warnings and Precautions (5.1)], reserve FIORINAL with CODEINE for use in patients for whom alternative treatment options (e.g., non-opioid, non-barbiturate analgesics):  
- Have not been tolerated, or are not expected to be tolerated;  
- Have not provided adequate analgesia, or are not expected to provide adequate analgesia.

**DOSAGE AND ADMINISTRATION**

2.1 Important Dosage and Administration Instructions

Use the lowest effective dosage for the shortest duration consistent with individual patient treatment goals [see Warnings and Precautions (5)].  

Initiate the dosing regimen for each patient individually, taking into account the patient's severity of pain, patient response, prior analgesic treatment experience, and risk factors for addiction, abuse, and misuse [see Warnings and Precautions (5.1)].

2.2 Dosing Information

One or two capsules every 4 hours. Total daily dosage should not exceed 6 capsules.

**WARNINGS AND PRECAUTIONS**

5.1 Addiction, Abuse, and Misuse

FIORINAL with CODEINE exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk prior to prescribing FIORINAL with CODEINE, and monitor all patients regularly for the development of these behaviors and conditions [see Warnings and Precautions (5.1)].

5.2 Life-Threatening Respiratory Depression

Serious, life-threatening, or fatal respiratory depression may occur with use of FIORINAL with CODEINE. Monitor for respiratory depression, especially during initiation of FIORINAL with CODEINE or following a dose increase [see Warnings and Precautions (5.2)].

5.3 Accidental Ingestion

Accidental ingestion of even one dose of FIORINAL with CODEINE, especially by children, can result in a fatal overdose of FIORINAL with CODEINE [see Warnings and Precautions (5.2)].

5.4 Risks From Concomitant Use With Benzodiazepines Or Other CNS Depressants

Concomitant use of opioids with benzodiazepines or other central nervous system (CNS) depressants, including alcohol, may result in profound sedation, respiratory depression, coma, and death [see Warnings and Precautions (5.3), Drug Interactions (7)].

- Reserve concomitant prescribing of FIORINAL with CODEINE and benzodiazepines or other CNS depressants for use in patients for whom alternative treatment options are inadequate.
- Limit dosages and durations to the minimum required.
- Follow patients for signs and symptoms of respiratory depression and sedation.

5.5 Ultra-Rapid Metabolism of Codeine and Other Risk Factors for Life-Threatening Respiratory Depression in Children

Life-threatening respiratory depression and death have occurred in children who received codeine. Most of the reported cases occurred following tonsillectomy and/or adenoidectomy, and many of the children had evidence of being an ultra-rapid metabolizer of codeine due to a CYP2D6 polymorphism. [see Warnings and Precautions (5.4)]. FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications (4)]. Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.

5.6 Neonatal Opioid Withdrawal Syndrome

Prolonged use of FIORINAL with CODEINE during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated, and requires management according to protocols developed by neonatology experts. If opioid use is required for a prolonged period in a pregnant woman, advise the patient of the risk of neonatal opioid withdrawal syndrome and ensure that appropriate treatment will be available [see Warnings and Precautions (5.5)].

5.7 Interactions with Drugs Affecting Cytochrome P450 Isoenzymes

The effects of concomitant use or discontinuation of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with codeine due to a CYP2D6 polymorphism. [see Warnings and Precautions (5.4)]. FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications (4)]. Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.

Life-threatening respiratory depression and death have occurred in children who received codeine. Most of the reported cases occurred following tonsillectomy and/or adenoidectomy, and many of the children had evidence of being an ultra-rapid metabolizer of codeine due to a CYP2D6 polymorphism. [see Warnings and Precautions (5.4)]. FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications (4)]. Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.

Neonatal Opioid Withdrawal Syndrome

Prolonged use of FIORINAL with CODEINE during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated, and requires management according to protocols developed by neonatology experts. If opioid use is required for a prolonged period in a pregnant woman, advise the patient of the risk of neonatal opioid withdrawal syndrome and ensure that appropriate treatment will be available [see Warnings and Precautions (5.5)].

Interactions with Drugs Affecting Cytochrome P450 Isoenzymes

The effects of concomitant use or discontinuation of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with codeine due to a CYP2D6 polymorphism. [see Warnings and Precautions (5.4)]. FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications (4)]. Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.

Neonatal Opioid Withdrawal Syndrome

Prolonged use of FIORINAL with CODEINE during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated, and requires management according to protocols developed by neonatology experts. If opioid use is required for a prolonged period in a pregnant woman, advise the patient of the risk of neonatal opioid withdrawal syndrome and ensure that appropriate treatment will be available [see Warnings and Precautions (5.5)].

Interactions with Drugs Affecting Cytochrome P450 Isoenzymes

The effects of concomitant use or discontinuation of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with codeine due to a CYP2D6 polymorphism. [see Warnings and Precautions (5.4)]. FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications (4)]. Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.

Neonatal Opioid Withdrawal Syndrome

Prolonged use of FIORINAL with CODEINE during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated, and requires management according to protocols developed by neonatology experts. If opioid use is required for a prolonged period in a pregnant woman, advise the patient of the risk of neonatal opioid withdrawal syndrome and ensure that appropriate treatment will be available [see Warnings and Precautions (5.5)].

Interactions with Drugs Affecting Cytochrome P450 Isoenzymes

The effects of concomitant use or discontinuation of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with codeine due to a CYP2D6 polymorphism. [see Warnings and Precautions (5.4)]. FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications (4)]. Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.

Neonatal Opioid Withdrawal Syndrome

Prolonged use of FIORINAL with CODEINE during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated, and requires management according to protocols developed by neonatology experts. If opioid use is required for a prolonged period in a pregnant woman, advise the patient of the risk of neonatal opioid withdrawal syndrome and ensure that appropriate treatment will be available [see Warnings and Precautions (5.5)].

Interactions with Drugs Affecting Cytochrome P450 Isoenzymes

The effects of concomitant use or discontinuation of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with codeine due to a CYP2D6 polymorphism. [see Warnings and Precautions (5.4)]. FIORINAL with CODEINE is contraindicated in children younger than 12 years of age and in children younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications (4)]. Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine.
2.3 Discontinuation of Fiorinal with Codeine

While not indicated for around-the-clock therapy, when a patient who has been taking Fiorinal with Codeine regularly and may be physically dependent no longer requires therapy with Fiorinal with Codeine, taper the dose gradually, by 25% to 50% every 2 to 4 days, while monitoring carefully for signs and symptoms of withdrawal. If the patient develops these signs or symptoms, raise the dose to the previous level and taper more slowly, either by increasing the interval between decreases, decreasing the amount of change in dose, or both. Do not abruptly discontinue Fiorinal with Codeine in a physically dependent patient (see Warnings and Precautions (5.14), Drug Abuse and Dependence (5.3)).

3 DOSAGE FORMS AND STRENGTHS

Capsules: Butalbital, 50 mg, Aspirin, 325 mg, Caffeine, 40 mg, Codeine Phosphate, 30 mg

Blue cap with a yellow body. Cap is imprinted twice with “Fiorinal” and “Codeine” in red. Body is imprinted twice with “WATSON 956” in red.

4 CONTRAINDICATIONS

Fiorinal with Codeine is contraindicated for:
- All children younger than 12 years of age (see Warnings and Precautions (5.4))
- Postoperative management in children younger than 18 years of age following tonsillectomy and/or adenoidectomy (see Warnings and Precautions (5.4)).

Fiorinal with Codeine is also contraindicated in patients with:
- Significant respiratory depression (see Warnings and Precautions (5.7))
- Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment (see Warnings and Precautions (5.7))
- Concurrent use of monoamine oxidase inhibitors (MAOIs) or use of MAOIs within the last 14 days (see Warnings and Precautions (5.8)/Drug Interactions (7)).
- Known or suspected gastrointestinal obstruction, including paralytic ileus (see Warnings and Precautions (5.12))
- Hypersensitivity or intolerance to aspirin, caffeine, butalbital, or codeine.
- Hemophilia (see Warnings and Precautions (5.16))
- Reye’s Syndrome (see Warnings and Precautions (5.17))
- Known allergy to nonsteroidal anti-inflammatory drugs (NSAIDs) (see Warnings and Precautions (5.18))
- Syndrome of asthma, rhinitis, and nasal polyps (see Warnings and Precautions (5.18))

5 WARNINGS AND PRECAUTIONS

5.1 Addiction, Abuse, and Misuse

Fiorinal with Codeine contains codeine. Codeine in combination with butalbital, aspirin, and caffeine is a Schedule III controlled substance. As Fiorinal with Codeine contains butalbital and codeine, it exposes users to the risks of addiction, abuse, and misuse (see Drug Abuse and Dependence [9]).

Although the risk of addiction in any individual is unknown, it can occur in patients appropriately prescribed Fiorinal with Codeine. Addiction can occur at recommended dosages and if the drug is misused or abused.

Assess each patient’s risk for addiction, abuse, or misuse prior to prescribing Fiorinal with Codeine, and monitor all patients receiving Fiorinal with Codeine for the development of these behaviors and conditions. Risks are increased in patients with a personal or family history of substance abuse (including drug or alcohol abuse or addiction) or mental illness (e.g., major depression). The potential for these risks should not, however, prevent the proper management of pain in any given patient. Patients at increased risk may be prescribed opioids such as Fiorinal with Codeine, but use in such patients necessitates intensive counseling about the risks and proper use of Fiorinal with Codeine along with intensive monitoring for signs of addiction, abuse, and misuse.

Opioids and barbiturates are sought by drug abusers and people with addiction disorders and are subject to criminal diversion. Consider these risks when prescribing or dispensing Fiorinal with Codeine. Strategies to reduce these risks include prescribing the drug in the smallest appropriate quantity and advising the patient on the proper disposal of unused drug (see Patient Counseling Information (17)). Contact local state professional licensing board or state controlled substances authority for information on how to prevent and detect abuse or diversion of this product.

5.2 Life-Threatening Respiratory Depression

Serious, life-threatening, or fatal respiratory depression has been reported with the use of opioids, even when used as recommended. Respiratory depression, if not immediately recognized and treated, may lead to respiratory arrest and death. Management of respiratory depression may include close observation, supportive measures, and use of opioid antagonists, depending on the patient’s clinical status (see Overdose (10)). Carbon dioxide (CO\textsubscript{2}) retention from opioid-induced respiratory depression can exacerbate the sedating effects of opioids.

While serious, life-threatening, or fatal respiratory depression can occur at any time during the use of Fiorinal with Codeine, the risk is greatest during the initiation of therapy or following a dosage increase. Monitor patients closely for respiratory depression, especially within the first 24-72 hours of initiating therapy with and following dosage increases of Fiorinal with Codeine.

To reduce the risk of respiratory depression, proper dosing and titration of Fiorinal with Codeine are essential (see Dosage and Administration (2.1)). Overestimating the Fiorinal with Codeine dosage when converting patients from another opioid product can result in a fatal overdose with the first dose.

Accidental ingestion of Fiorinal with Codeine, especially by children, can result in respiratory depression and death due to an overdose of codeine and butalbital.

5.3 Risks from Concomitant Use with Benzodiazepines or Other CNS depressants
Respiratory Depression in Children

Life-threatening respiratory depression and death have occurred in children who received codeine. Codeine is subject to variability in metabolism based upon CYP2D6 genotype (described below), which can lead to an increased exposure to the active metabolite morphine. Based upon postmarketing reports, children younger than 12 years old appear to be more susceptible to the respiratory depressant effects of codeine, particularly if there are risk factors for respiratory depression. For example, many reported cases of death occurred in the post-operative period following tonsillectomy and/or adenoidectomy, and many of the children had evidence of being ultra-rapid metabolizers of codeine. Furthermore, children with obstructive sleep apnea who are treated with codeine for post-tonsillectomy and/or adenoidectomy pain may be particularly sensitive to its respiratory depressant effect. Because of the risk of life-threatening respiratory depression and death:

- **FIORINAL with CODEINE is contraindicated for all children younger than 12 years of age** (see Contraindications (4)).
- **FIORINAL with CODEINE is contraindicated for post-operative management in pediatric patients younger than 18 years of age following tonsillectomy and/or adenoidectomy** (see Contraindications (4)).
- **Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine unless the benefits outweigh the risks. Risk factors include conditions associated with hypoventilation, such as postoperative status, obstructive sleep apnea, obesity, severe pulmonary disease, neuromuscular disease, and concomitant use of other medications that cause respiratory depression.**
- **As with adults, when prescribing FIORINAL with CODEINE for adolescents, healthcare providers should choose the lowest effective dose for the shortest period of time and inform patients and caregivers about these risks and the signs of morphine overdose** (see Use in Specific Populations (8.4), Overdosage (10)).

Nursing Mothers

At least one death was reported in a nursing infant who was exposed to high levels of morphine in breast milk because the mother was an ultra-rapid metabolizer of codeine. Breastfeeding is not recommended during treatment with FIORINAL with CODEINE (see Use in Specific Populations (8.2)).

CYP2D6 Genetic Variability: Ultra-rapid metabolizer

Some individuals may be ultra-rapid metabolizers because of a specific CYP2D6 genotype (gene duplications denoted as *1*/*1*N or *1*/*2*N). The prevalence of this CYP2D6 phenotype varies widely and has been estimated at 1 to 10% for Whites (European, North American), 3 to 4% for Blacks (African American), 1 to 2% for East Asians (Chinese, Japanese, Korean), and may be greater than 10% in certain racial/ethnic groups (i.e., Oceanian, Northern African, Middle Eastern, Ashkenazi Jews, Puerto Rican). These individuals convert codeine into its active metabolite, morphine, more rapidly and completely than other people. This rapid conversion results in higher than expected serum morphine levels. Even at labeled dosage regimen, individuals who are ultra-rapid metabolizers may have life-threatening or fatal respiratory depression or experience signs of overdose (such as extreme sleepiness, confusion, or shallow breathing) (see Overdosage (10)). Therefore, individuals who are ultra-rapid metabolizers should not use FIORINAL with CODEINE.

5.5 Neonatal Opioid Withdrawal Syndrome

Prolonged use of FIORINAL with CODEINE during pregnancy can result in withdrawal in the neonate. Neonatal opioid withdrawal syndrome, unlike opioid withdrawal syndrome in adults, may be life-threatening if not recognized and treated, and requires management according to protocols developed by neonatology experts. Observe newborns for signs of neonatal opioid withdrawal syndrome and manage accordingly. Advise pregnant women using opioids for a prolonged period of the risk of neonatal opioid withdrawal syndrome and ensure that appropriate treatment will be available (see Use in Specific Populations (8.1, 8.2), Patient Counseling Information).

5.6 Risks of Interactions with Drugs Affecting Cytochrome P450 Isoenzymes

The effects of concomitant use or discontinuation of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with codeine are complex. Use of cytochrome P450 3A4 inducers, 3A4 inhibitors, or 2D6 inhibitors with FIORINAL with CODEINE requires careful consideration of the effects on codeine and the active metabolite, morphine.

* Cytochrome P450 3A4 Interaction
The concomitant use of FIORINAL with CODEINE with all cytochrome P450 3A4 inhibitors, such as macrolide antibiotics (e.g., erythromycin), azole-antifungal agents (e.g., ketoconazole), and protease inhibitors (e.g., ritonavir) or discontinuation of a cytochrome P450 3A4 inducer such as rifampin, carbamazepine, and phenytoin, may result in an increase in codeine plasma concentrations with subsequent greater metabolism by cytochrome P450 2D6, resulting in greater morphine levels, which could increase or prolong adverse reactions and may cause potentially fatal respiratory depression.

The concomitant use of FIORINAL with CODEINE with all cytochrome P450 3A4 inducers or discontinuation of a cytochrome P450 3A4 inhibitor may result in lower codeine levels, greater norcodeine levels, and less metabolism via 2D6 with resultant lower morphine levels. This may be associated with a decrease in efficacy, and in some patients, may result in signs and symptoms of opioid withdrawal.

Follow patients receiving FIORINAL with CODEINE and any CYP3A4 inhibitor or inducer for signs and symptoms that may reflect opioid toxicity and opioid withdrawal when FIORINAL with CODEINE is used in conjunction with inhibitors and inducers of CYP3A4.

If concomitant use of a CYP3A4 inhibitor is necessary or if a CYP3A4 inducer is discontinued, consider dosage reduction of FIORINAL with CODEINE until stable drug effects are achieved. Monitor patients for respiratory depression and sedation at frequent intervals.

If concomitant use of a CYP3A4 inducer is necessary or if a CYP3A4 inhibitor is discontinued, consider increasing the FIORINAL with CODEINE dosage until stable drug effects are achieved. Monitor for signs of opioid withdrawal. [Drug Interactions (7)].

5.7 Life-Threatening Respiratory Depression in Patients with Chronic Pulmonary Disease or in Elderly, Cachectic, or Debilitated Patients

The use of FIORINAL with CODEINE in patients with acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment is contraindicated.

Patients with Chronic Pulmonary Disease: FIORINAL with CODEINE-treated patients with significant chronic obstructive pulmonary disease or cor pulmonale, and those with a substantially decreased respiratory reserve, hypoxia, hypercapnia, or pre-existing respiratory depression are at increased risk of decreased respiratory drive including apnea, even at recommended dosages of FIORINAL with CODEINE (see Warnings and Precautions (5.7)).

Elderly, Cachectic, or Debilitated Patients: Life-threatening respiratory depression is more likely to occur in elderly, cachectic, or debilitated patients because they may have altered pharmacokinetics or altered clearance compared to younger, healthier patients (see Warnings and Precautions (5.7)). Monitor such patients closely, particularly when initiating and titrating FIORINAL with CODEINE and when FIORINAL with CODEINE is given concomitantly with other drugs that depress respiration (see Warnings and Precautions (5.7)). Alternatively, consider the use of non-opioid analgesics in these patients.

5.8 Interaction with Monoamine Oxidase Inhibitors

Monoamine oxidase inhibitors (MAOIs) may potentiate the effects of morphine, codeine’s active metabolite, including respiratory depression, coma, and confusion. FIORINAL with CODEINE should not be used in patients taking MAOIs or within 14 days of stopping such treatment.

5.9 Adrenal Insufficiency

Cases of adrenal insufficiency have been reported with opioid use, more often following greater than one month of use. Presentation of adrenal insufficiency may include non-specific symptoms and signs including nausea, vomiting, anorexia, fatigue, weakness, dizziness, and low blood pressure. If adrenal insufficiency is suspected, confirm the diagnosis with diagnostic testing as soon as possible. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids. Wean the patient off of the opioid to allow adrenal function to recover and continue corticosteroid treatment until adrenal function recovers. Other opioids may be tried as some cases reported use of a different opioid without recurrence of adrenal insufficiency. The information available does not identify any particular opioids as being more likely to be associated with adrenal insufficiency.

5.10 Severe Hypotension

FIORINAL with CODEINE may cause severe hypotension including orthostatic hypotension and syncope in ambulatory patients. There is increased risk in patients whose ability to maintain blood pressure has already been compromised by a reduced blood volume or concurrent administration of certain CNS depressant drugs (e.g., phenothiazines or general anesthetics) [Drug Interactions (7)]. Monitor these patients for signs of hypotension after initiating or titrating the dosage of FIORINAL with CODEINE. In patients with circulatory shock, FIORINAL with CODEINE may cause vasodilation that can further reduce cardiac output and blood pressure. Avoid the use of FIORINAL with CODEINE in patients with circulatory shock.

5.11 Risks of Use in Patients with Increased Intracranial Pressure, Brain Tumors, Head Injury, or Impaired Consciousness

In patients who may be susceptible to the intracranial effects of CO₂ retention (e.g., those with evidence
of increased intracranial pressure or brain tumors), FIORINAL with CODEINE may reduce respiratory drive, and the resultant CO2 retention can further increase intracranial pressure. Monitor such patients for signs of sedation and respiratory depression, particularly when initiating therapy with FIORINAL with CODEINE.

Opioids may also obscure the clinical course in a patient with a head injury. Avoid the use of FIORINAL with CODEINE in patients with impaired consciousness or coma.

5.12 Risks of Use in Patients with Gastrointestinal Conditions Including Peptic Ulcer Disease

FIORINAL with CODEINE is contraindicated in patients with known or suspected gastrointestinal obstruction, including paralytic ileus.

The codeine in FIORINAL with CODEINE may cause spasm of the sphincter of Oddi. Opioids may cause increases in serum amylase. Monitor patients with biliary tract disease, including acute pancreatitis for worsening symptoms.

Patients with a history of active peptic ulcer disease should avoid using aspirin, which can cause gastric mucosal irritation and bleeding.

The aspirin in FIORINAL with CODEINE can cause GI side effects including stomach pain, heartburn, nausea, vomiting, and gross GI bleeding. Although minor upper GI symptoms, such as dyspepsia, are common and can occur anytime during therapy, physicians should remain alert for signs of ulceration and bleeding, even in the absence of previous GI symptoms. Physicians should inform patients about the signs and symptoms of GI side effects and what steps to take if they occur.

5.13 Increased Risk of Seizures in Patients with Seizure Disorders

The codeine in FIORINAL with CODEINE may increase the frequency of seizures in patients with seizure disorders, and may increase the risk of seizures occurring in other clinical settings associated with seizures. Monitor patients with a history of seizure disorders for worsened seizure control during FIORINAL with CODEINE therapy.

5.14 Withdrawal

Avoid the use of mixed agonist/antagonist (e.g., pentazocine, nalorphine, and butorphanol) or partial agonist (e.g., buprenorphine) analgesics in patients who are receiving a full opioid agonist analgesic, including FIORINAL with CODEINE. In these patients, mixed agonist/antagonist and partial agonist analgesics may reduce the analgesic effect and/or precipitate withdrawal symptoms.

When discontinuing FIORINAL with CODEINE in a physically-dependent patient, gradually taper the dosage [see Dosage and Administration (2.3)]. Do not abruptly discontinue FIORINAL with CODEINE in these patients [see Drug Abuse and Dependence (9.2, 9.3)].

5.15 Risks of Driving and Operating Machinery

FIORINAL with CODEINE may impair the mental or physical abilities needed to perform potentially hazardous activities such as driving a car or operating machinery. Warn patients not to drive or operate dangerous machinery unless they are tolerant to the effects of FIORINAL with CODEINE and know how they will react to the medication.

5.16 Coagulation Abnormalities and Bleeding Risks

Even low doses of aspirin can inhibit platelet function leading to an increase in bleeding time. This can adversely affect patients with inherited (i.e. hemophilia) or acquired (i.e. liver disease or vitamin K deficiency) bleeding disorders. Aspirin is contraindicated in patients with hemophilia.

Aspirin administered pre-operatively may prolong the bleeding time.

Patients who consume three or more alcoholic drinks every day should be counseled about the bleeding risks involved with chronic, heavy alcohol use while taking aspirin.

5.17 Reye’s Syndrome

Aspirin should not be used in children or teenagers for viral infections, with or without fever, because of the risk of Reye syndrome with concomitant use of aspirin in certain viral illnesses.

5.18 Allergy

Aspirin is contraindicated in patients with known allergy to nonsteroidal anti-inflammatory drug (NSAIDs) and in patients with the syndrome of asthma, rhinitis, and nasal polyps. Aspirin may cause severe urticaria, angioedema, or bronchospasm (asthma).

5.19 Drug/Laboratory Test Interactions

Aspirin: Aspirin may interfere with the following laboratory determinations in blood: serum amylase, fasting blood glucose, cholesterol, protein, serum glutamic-oxaloacetic transaminase (SGOT), uric acid, prothrombin time and bleeding time. Aspirin may interfere with the following laboratory determinations in urine: glucose, 5-hydroxy-indoleacetic acid, Gerhardt ketone, vanillylmandelic acid (VMA), uric acid, diactic acid, and spectrophotometric detection of barbiturates.

Codeine: Codeine may increase serum amylase levels.

6 ADVERSE REACTIONS

The following serious adverse reactions are described, or described in greater detail, in other sections:

- Addiction, Abuse, and Misuse [see Warnings and Precautions (5.1)]
- Life-Threatening Respiratory Depression [see Warnings and Precautions (5.2)]
- Interactions with Benzodiazepines or Other CNS Depressants [see Warnings and Precautions (5.3)]
- Ultra-Rapid Metabolism of Codeine and Other Risk Factors for Life-Threatening Respiratory Depression in Children [see Warnings and Precautions (5.4)]
- Neonatal Opioid Withdrawal Syndrome [see Warnings and Precautions (5.5)]
- Adrenal Insufficiency [see Warnings and Precautions (5.9)]
- Severe Hypotension [see Warnings and Precautions (5.10)]
- Gastrointestinal Adverse Reactions [see Warnings and Precautions (5.12)]
- Seizures [see Warnings and Precautions (5.13)]
- Withdrawal [see Warnings and Precautions (5.14)]
- Coagulation Abnormalities and Bleeding [see Warnings and Precautions (5.16)]
- Reye’s Syndrome [see Warnings and Precautions (5.17)]
6.1 Clinical Trials Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice.

Incidence in Controlled Clinical Trials

The following table summarizes the incidence rates of the adverse events reported by at least 1% of the FIORINAL with CODEINE treated patients in controlled clinical trials comparing FIORINAL with CODEINE to placebo, and provides a comparison to the incidence rates reported by the placebo-treated patients.

The prescriber should be aware that these figures cannot be used to predict the incidence of side effects in the course of usual medical practice where patient characteristics and other factors differ from those that prevailed in the clinical trials. Similarly, the cited frequencies cannot be compared with figures obtained from other clinical investigations involving different treatments, uses, and investigators.

Other Adverse Events Reported During Controlled Clinical Trials

The listing that follows represents the proportion of the 382 patients exposed to FIORINAL with CODEINE while participating in the controlled clinical trials who reported, on at least one occasion, an adverse event of the type cited. All reported adverse events, except those already presented in the previous table, are included. It is important to emphasize that, although the adverse events reported did occur while the patient was receiving FIORINAL with CODEINE, the adverse events were not necessarily caused by FIORINAL with CODEINE.

Adverse events are classified by body system and frequency. “Frequent” is defined as an adverse event which occurred in at least 1/100 (1%) of the patients; all adverse events listed in the previous table are frequent. “Infrequent” is defined as an adverse event that occurred in less than 1/100 patients but at least 1/1000 patients. All adverse events tabulated below are classified as infrequent.

Central Nervous: headache, shaky feeling, tingling, agitation, fainting, fatigue, heavy eyelids, high energy, hot spells, numbness, and sluggishness.

Autonomic Nervous: dry mouth and hyperhidrosis.

Gastrointestinal: vomiting, difficulty swallowing, and heartburn.

Cardiovascular: tachycardia.

Musculoskeletal: leg pain and muscle fatigue.

Genitourinary: diuresis.

Miscellaneous: pruritus, fever, earache, nasal congestion, and tinnitus.

The following adverse drug reactions have been reported with the components of FIORINAL with CODEINE. Potential effects of high dosage are listed in the see OVERDOSAGE section of this insert.

Aspirin: occult blood loss, hemolytic anemia, iron deficiency anemia, gastric distress, heartburn, nausea, peptic ulcer, prolonged bleeding time, acute airway obstruction, renal toxicity when taken in high doses for prolonged periods, impaired urate excretion, hepatitis.

Caffeine: cardiac stimulation, irritability, tremor, dependence, nephrotoxicity, hyperglycemia.

Codeine: nausea, vomiting, drowsiness, lightheadedness, constipation, pruritus.

6.2 Postmarketing Experience

The following adverse reactions have been identified during post approval use of FIORINAL with CODEINE. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

Central Nervous: abuse, addiction, anxiety, depression, disorientation, hallucination, hyperactivity, insomnia, libido decrease, nervousness, neuropathy, psychosis, sedation, sexual activity increase, slurred speech, twitching, unconsciousness, vertigo.

Autonomic Nervous: epistaxis, flushing, miosis, salivation.

Gastrointestinal: anorexia, appetite increased, constipation, diarrhea, esophagitis, gastroenteritis, gastrointestinal spasm, hiccups, mouth burning, pyloric ulcer.

Cardiovascular: chest pain, hypotensive reaction, palpitations, syncope.

Skin: erythema, erythema multiforme, exfoliative dermatitis, hives, rash, toxic epidermal necrolysis.

Urinary: kidney impairment, urinary difficulty.

Miscellaneous: allergic reaction, anaphylactic shock, cholangiocarcinoma, drug interaction with erythromycin (stomach upset), edema.
Table 1 includes clinically significant drug interactions with FIORINAL with CODEINE.

<table>
<thead>
<tr>
<th>Inhibitors of CYP3A4</th>
<th>Clinical Impact</th>
<th>Interventions</th>
<th>Impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clinical Impact:</td>
<td>The concomitant use of FIORINAL with CODEINE with CYP3A4 inhibitors may result in an increase in codeine plasma concentrations with subsequently greater metabolism by cytochrome CYP2D6, resulting in lower morphine levels, which could increase or prolong adverse reactions and may cause potentially fatal respiratory depression, particularly when an inhibitor is added after a stable dose of FIORINAL with CODEINE is achieved. After stopping a CYP3A4 inhibitor, as the effects of the inhibitor decline, it may result in lower codeine levels, greater norcodeine levels, and less metabolism to 2D6 with resultant lower morphine levels (see Clinical Pharmacology [12.3]), resulting in decreased opioid efficacy or a withdrawal syndrome in patients who had developed physical dependence to codeine.</td>
<td>If concomitant use with CYP3A4 inhibitor is necessary, consider dosage reduction of FIORINAL with CODEINE until stable drug effects are achieved. Monitor patients for respiratory depression and sedation at frequent intervals.</td>
<td>If a CYP3A4 inhibitor is discontinued, consider increasing the FIORINAL with CODEINE dosage until stable drug effects are achieved. Monitor for signs of opioid withdrawal.</td>
</tr>
<tr>
<td>Examples</td>
<td>Macrolide antibiotics (e.g., erythromycin), azole-antifungal agents (e.g., ketoconazole), protease inhibitors (e.g., ritonavir)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CYP3A4 Inducers</td>
<td>The concomitant use of FIORINAL with CODEINE and CYP3A4 inducers can result in lower codeine levels, greater norcodeine levels, and less metabolism via 2D6 with resultant lower morphine levels (see Clinical Pharmacology [12.3]), resulting in decreased efficacy or onset of a withdrawal syndrome in patients who have developed physical dependence (see Warnings and Precautions [5.14]). After stopping a CYP3A4 inhibitor, as the effects of the inhibitor decline, the codeine plasma concentration may increase with subsequently greater metabolism by cytochrome CYP2D6, resulting in greater morphine levels (see Clinical Pharmacology [12.3]), which could increase or prolong both the therapeutic effects and adverse reactions, and may cause serious respiratory depression.</td>
<td>If concomitant use of a CYP3A4 inhibitor is necessary, follow the patient for reduced efficacy and signs of opioid withdrawal and consider increasing the FIORINAL with CODEINE dosage as needed.</td>
<td>If a CYP3A4 inhibitor is discontinued, consider FIORINAL with CODEINE dosage reduction and monitor for signs of respiratory depression and sedation at frequent intervals.</td>
</tr>
<tr>
<td>Inhibitors of CYP2D6</td>
<td>Codeine in FIORINAL with CODEINE is metabolized by CYP2D6 to form morphine. The concomitant use of FIORINAL with CODEINE and CYP2D6 inhibitors can increase the plasma concentration of codeine, but can decrease the plasma concentrations of active metabolite morphine which could result in reduced analgesic efficacy or symptoms of opioid withdrawal, particularly when an inhibitor is added after a stable dose of FIORINAL with CODEINE is achieved (see Clinical Pharmacology [12.3]). After stopping a CYP2D6 inhibitor, as the effects of the inhibitor decline, the codeine plasma concentration will decrease but the active metabolite morphine plasma concentration will increase, which could increase or prolong adverse reactions and may cause potentially fatal respiratory depression (see Clinical Pharmacology [12.3]).</td>
<td>If concomitant use with a CYP2D6 inhibitor is necessary, or if a CYP2D6 inhibitor is discontinued after concomitant use, consider dosage adjustment of FIORINAL with CODEINE and monitor patients closely at frequent intervals.</td>
<td>If concomitant use with CYP2D6 inhibitors is necessary, follow the patient for reduced efficacy or signs and symptoms of opioid withdrawal and consider increasing the FIORINAL with CODEINE as needed.</td>
</tr>
<tr>
<td>Intervention:</td>
<td></td>
<td></td>

### Benzodiazepines and other Central Nervous System (CNS) Depressants

**Clinical**/Due to additive pharmacologic effect, the concomitant use of benzodiazepines or other CNS depressants including alcohol, increases the risk of respiratory depression, profound sedation, coma, and death. **Impact:** Reserve concomitant prescribing of these drugs for use in patients for whom alternative treatment options are inadequate. Limit dosages and durations to the minimum required. Follow patients closely for signs of respiratory depression and sedation (see Warnings and Precautions [5.3]). **Examples:** Benzodiazepines and other sedatives/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol.

### Serotonergic Drugs

**Clinical**/Due to additive pharmacologic effect, the concomitant use of serotonergic drugs with other drugs that affect the serotonin neurotransmitter system has resulted in serotonin syndrome. **Impact:** If urgent use of an opioid is necessary, use test doses and frequent titration of small doses of other opioids (such as oxycodone, hydrocodone, oxymorphone, hydrocodone, or buprenorphine) to treat pain while closely monitoring blood pressure and signs and symptoms of CNS and respiratory depression. **Examples:** phenelzine, tranylcypromine, linezolid

### MAOIs

**Clinical**/MAOI interactions with opioids may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma) (see Warnings and Precautions [5.8]). **Impact:** Do not use FIORINAL with CODEINE in patients taking MAOIs or within 14 days of stopping such treatment. **Examples:** phenelzine, tranylcypromine, linezolid

**Mixed Agonist/Antagonist and Partial Agonist Opioid Analgesics**

**Clinical**/May reduce the analgesic effect of FIORINAL with CODEINE and precipitate withdrawal symptoms. **Impact:** Avoid concomitant use.
In animal reproduction studies, codeine administration during organogenesis has been shown to produce delayed ossification in the fetus.

Diuretics

Clinical: Opioids can reduce the efficacy of diuretics by inducing the release of antidiuretic hormone.
Impact: Monitor patients for signs of diminished diuresis and/or effects on blood pressure and increase the dosage of the diuretic as needed.

Intervention: The effectiveness of diuretics in patients with underlying renal or cardiovascular disease may be diminished by the concomitant administration of aspirin due to inhibition of renal prostaglandins, leading to decreased renal blood flow and salt and fluid retention.

Anticholinergic Drugs

Clinical: The concomitant use of anticholinergic drugs may increase risk of urinary retention and/or severe constipation, which may lead to paralytic ileus.
Impact: Monitor patients for signs of urinary retention or reduced gastric motility when FIORINAL with CODEINE is used concomitantly with anticholinergic drugs.

Intervention: Monitor patients for signs of bleeding.
Examples: Warfarin, heparin, enoxaparin, clopidogrel, prasugrel, rivaroxaban, apixaban

Uricosuric Agents

Clinical: Aspirin inhibits the uricosuric effects of uricosuric agents.
Impact: Avoid concomitant use.

Examples: Probenecid

Carbonic Anhydrase Inhibitors

Clinical: Concurrent use with aspirin can lead to high serum concentrations of the carbonic anhydrase inhibitor and cause toxicity due to competition at the renal tubule for its binding sites and/or reducing its renal clearance.
Impact: Monitor patients for signs of hyperuricemia and adjust the dose of the carbonic anhydrase inhibitor as needed.

Intervention: Closely monitor the renal function of patients receiving concomitant use.
Examples: Acetazolamide, methazolamide

Methotrexate

Clinical: Aspirin may enhance the toxicity of methotrexate by displacing it from its plasma protein binding sites and/or reducing its renal clearance.
Impact: Use caution if using concomitantly, especially in elderly patients or patients with renal impairment. Monitor patients for methotrexate toxicity.

Intervention: Use caution if using concomitantly.
Examples: Methotrexate

Nephrotoxic Agents

Clinical: Concomitant use with aspirin may lead to additive nephrotoxicity due to the inhibition of renal prostaglandins by aspirin. Also, the plasma concentration of aspirin is increased by conditions that reduce the glomerular filtration rate or tubular secretion.
Impact: Monitor the blood pressure and renal function of patients receiving concomitant use.

Intervention: Use caution if using concomitantly with nephrotoxic agents. Closely monitor the renal function of patients receiving concomitant use.
Examples: Amphotericin B, gentamicin, cisplatin, cyclosporine, foscarnet, or parenteral vancomycin

Angiotensin Converting Enzyme (ACE) Inhibitors

Clinical: The hypotensive and hypotensive effects of ACE inhibitors may be diminished by the concomitant administration of aspirin due to its indirect effect on the renin-angiotensin-aldosterone system.
Impact: Monitor the blood pressure and renal function of patients.

Intervention: Use caution if using concomitantly.
Examples: Ramipril, captopril

Beta Blockers

Clinical: The hypotensive effects of beta blockers may be diminished by the concomitant administration of aspirin due to inhibition of renal prostaglandins, leading to decreased renal blood flow and salt and fluid retention.
Impact: Use caution if using concomitantly.

Intervention: Use caution if using concomitantly. Monitor the blood pressure and renal function of patients receiving concomitant use.
Examples: Metoprolol, propranolol

Hypoglycemic Agents

Clinical: Aspirin may increase the serum glucose-lowering action of insulin and sulfonylureas leading to hypoglycemia.
Impact: Patients should be advised to consult a physician if any signs or symptoms of hypoglycemia occur.

Intervention: Use caution if using concomitantly.
Examples: Insulin, glimepiride, glipizide

Anticonvulsants

Clinical: Aspirin can displace protein-bound phenytoin and valproic acid, leading to a decrease in the total concentration of phenytoin and an increase in serum valproic acid levels.
Impact: Use caution if using concomitantly.

Intervention: Use caution if using concomitantly.
Examples: Phenytoin, valproic acid

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

Clinical: Concurrent use with aspirin may increase the risk of bleeding or lead to decreased renal function. Aspirin may enhance serious side effects and toxicity of ketorolac by displacing it from its plasma protein binding sites and/or reducing its renal clearance.
Impact: Use caution if using concomitantly.

Intervention: Avoid concomitant use.
Examples: Ketorolac, ibuprofen, naproxen, diclofenac

Corticosteroids

Clinical: Concomitant use of corticosteroids and chronic use of aspirin, withdrawal of corticosteroids may result in salicylism because corticosteroids enhance renal clearance of salicylates and their withdrawal is followed by return to normal rates of renal clearance.
Impact: Use caution if using concomitantly.

Intervention: Avoid concomitant use

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

Prolonged use of opioid analgesics during pregnancy may cause neonatal opioid withdrawal syndrome. Use of aspirin, including FIORINAL with CODEINE, during the third trimester of pregnancy increases the risk of premature closure of the fetal ductus arteriosus.

Intervention: Avoid use of NSAIDs, including FIORINAL with CODEINE, in pregnant women starting at 30 weeks of gestation (third trimester). Available data with FIORINAL with CODEINE n pregnant women are insufficient to inform a drug-associated risk for major birth defects and miscarriage. Animal reproduction studies have not been conducted with the combination of butalbital, acetaminophen, caffeine, and codeine phosphate capsules or with butalbital alone. In animal reproduction studies, codeine administration during organogenesis has been shown to produce delayed ossification in the
No teratogenic effects were observed in rabbits administered up to 30 mg/kg (approximately 4 times the reportedly resulted in delayed ossification in the offspring.

In pregnant mice, a single 100 mg/kg dose (subcutaneous; approximately 2.8 times the recommended adult animal, were associated with an increase in embryo resorption at the time of implantation.

In studies in rats, doses at the 120 mg/kg level (oral; approximately 6 times the maximum recommended daily dose of 180 mg/day for adults on a mg/m basis) during organogenesis cranial malformations (i.e., meningoencephalocele) in several fetuses were observed; as well as the observation of increases in the percentage of resorptions per litter. Doses of 50 and 150 mg/kg, bid resulted in fetotoxicity as demonstrated by decreased fetal body weight. In an earlier study in hamsters, single oral doses of 73 to 360 mg/kg level on Gestation Day 8 (oral; approximately 4 to 16 times the maximum recommended daily dose of 180 mg/day for adults on a mg/m basis), reportedly produced craniostenosis in all of the fetuses examined.

In studies in rats, doses at the 120 mg/kg level (oral; approximately 6 times the maximum recommended daily dose of 180 mg/day for adults on a mg/m basis) during organogenesis, in the toxic range for the adult animal, were associated with an increase in embryo resorption at the time of implantation.

In pregnant mice, a single 100 mg/kg dose (subcutaneous; approximately 2.8 times the recommended daily dose of 180 mg/day for adults on a mg/m² basis) administered between Gestation Day 7 and 12 reportedly resulted in delayed ossification in the offspring.

No teratogenic effects were observed in rabbits administered up to 30 mg/kg (approximately 4 times the
drug therapy.

frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease or other

should be cautious, usually starting at the low end of the dosing range, reflecting the greater

effects of codeine. Because of the risk of life-threatening respiratory depression and death:

children with sleep apnea may be particularly sensitive to the respiratory depressant

codeine (i.e., multiple copies of the gene for cytochrome P450 isoenzyme 2D6 or high morphine

and/or adenoidectomy, and many of the children had evidence of being ultra-rapid metabolizers of

Life-threatening respiratory depression and death have occurred in children who received codeine

The safety and effectiveness of FIORINAL with CODEINE in pediatric patients have not been

viral illness. Safety and effectiveness in pediatric patients have not been established.

condition that affects the brain and liver and is most often observed in children given aspirin during a

withdrawal of NSAIDs, including aspirin, in women who have difficulties conceiving or who are

inhibitors has the potential to disrupt prostaglandin-mediated follicular rupture required for ovulation.

based on the mechanism of action, the use of prostaglandin-mediated NSAIDs, including aspirin, may

delay or prevent rupture of ovarian follicles, which has been associated with reversible infertility in

infertile women. Published animal studies have shown that administration of prostaglandin synthesis

inhibitors has the potential to disrupt prostaglandin-mediated follicular rupture required for ovulation.

Small studies in women treated with NSAIDs have also shown a reversible delay in ovulation. Consider

withdrawal of NSAIDs, including aspirin, in women who have difficulties conceiving or who are

undergoing investigation of infertility.

8.4 Pediatric Use

Preparations containing aspirin should be kept out of the reach of children. Reye's Syndrome is a rare

condition that affects the brain and liver and is most often observed in children given aspirin during a

viral illness. Safety and effectiveness in pediatric patients have not been established.

The safety and effectiveness of FIORINAL with CODEINE in pediatric patients have not been

established.

Life-threatening respiratory depression and death have occurred in children who received codeine [see

Warnings and Precautions (5.4)]. In most of the reported cases, these events followed tonsillectomy

and/or adenoidectomy, and many of the children had evidence of being ultra-rapid metabolizers of

codeine (i.e., multiple copies of the gene for cytochrome P450 isoenzyme 2D6 or high morphine

concentrations). Children with sleep apnea may be particularly sensitive to the respiratory depressant
effects of codeine. Because of the risk of life-threatening respiratory depression and death:

• FIORINAL with CODEINE is contraindicated for all children younger than 12 years of age
[see Contraindications (4)].

• FIORINAL with CODEINE is contraindicated for post-operative management in pediatric patients
younger than 18 years of age following tonsillectomy and/or adenoidectomy [see Contraindications
(4)].

• Avoid the use of FIORINAL with CODEINE in adolescents 12 to 18 years of age who have other
risk factors that may increase their sensitivity to the respiratory depressant effects of codeine unless
the benefits outweigh the risks. Risk factors include conditions associated with hypoventilation,
such as postoperative status, obstructive sleep apnea, obesity, severe pulmonary disease,
neuromuscular disease, and concomitant use of other medications that cause respiratory
depression [see Warnings and Precautions (5.4)].

8.5 Geriatric Use

Clinical studies of FIORINAL with CODEINE did not include sufficient numbers of subjects
aged 65 and over to determine whether they respond differently from younger subjects. Other
reported clinical experience has not identified differences in responses between the elderly and younger
patients. In general, dose selection for an elderly patient should be cautious, usually starting at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease or other

drug therapy.
Butalbital is known to be substantially excreted by the kidney, and the risk of toxic reactions to this drug may be greater in patients with impaired renal function. Because elderly patients are more likely to have decreased renal function, care should be taken in dose selection, and it may be useful to monitor renal function.

Elderly patients (aged 65 years or older) may have increased sensitivity to FIORINAL with CODEINE. In general, use caution when selecting a dosage for an elderly patient, usually starting at the low end of the dosage range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function and of concomitant disease or other drug therapy.

Respiratory depression is the chief risk for elderly patients treated with opioids, and has occurred after large initial doses were administered to patients who were not opioid-tolerant or when opioids were co-administered with other agents that depress respiration. Titrate the dosage of FIORINAL with CODEINE slowly in geriatric patients and monitor closely for signs of central nervous system and respiratory depression [see Warnings and Precautions (5.7)].

Components of this product are known to be substantially excreted by the kidney, and the risk of adverse reactions to this drug may be greater in patients with impaired renal function. Because elderly patients are more likely to have decreased renal function, care should be taken in dose selection, and it may be useful to monitor renal function.

Elderly patients, compared to younger patients, are at greater risk for NSAID-associated serious gastrointestinal, and/or renal adverse reactions. If the anticipated benefit for the elderly patient outweighs these potential risks, dose selection should start at the low end of the dosing range, and monitor patients for adverse effects [see Warnings and Precautions].

8.6 Hepatic Impairment

No formal studies have been conducted in patients with hepatic impairment so the pharmacokinetics of aspirin, codeine and butalbital in this patient population are unknown. Start these patients cautiously with lower doses of FIORINAL with CODEINE or with longer dosing intervals and titrate slowly while carefully monitoring for side effects. In patients with severe hepatic disease, monitor effects of therapy with serial liver function tests.

8.7 Renal Impairment

FIORINAL with CODEINE contains aspirin, which should be avoided in patients with severe renal failure (glomerular filtration rate less than 10 mL/minute).

Codeine pharmacokinetics may be altered in patients with renal failure. Clearance may be decreased and the metabolites may accumulate to much higher plasma levels in patients with renal failure as compared to patients with normal renal function. Start these patients cautiously with lower doses of FIORINAL with CODEINE or with longer dosing intervals and titrate slowly while carefully monitoring for side effects. In patients with renal disease, monitor effects of therapy with serial renal function tests.

9 DRUG ABUSE AND DEPENDENCE

9.1 Controlled Substance

FIORINAL with CODEINE contains codeine. Codeine in combination with butalbital, aspirin, and caffeine is a Schedule III controlled substance.

9.2 Abuse

FIORINAL with CODEINE contains codeine, a substance with a high potential for abuse similar to other opioids, including fentanyl, hydrocodone, hydromorphone, meperidine, morphine, oxycodone, oxymorphone, and tapentadol. FIORINAL with CODEINE can be abused and is subject to misuse, addiction, and criminal diversion [see Warnings and Precautions (5.1)].

All patients treated with opioids require careful monitoring for signs of abuse and addiction, because use of opioid analgesic products carries the risk of addiction even under appropriate medical use.

Prescription drug abuse is the intentional non-therapeutic use of a prescription drug, even once, for its rewarding psychological or physiological effects.

Drug addiction is a cluster of behavioral, cognitive, and physiological phenomena that develop after repeated substance use and includes: a strong desire to take the drug, difficulties in controlling its use, persisting in its use despite harmful consequences, a higher priority given to drug use than to other activities and obligations, increased tolerance, and sometimes a physical withdrawal.

“Drug-seeking” behavior is very common in persons with substance use disorders. Drug-seeking tactics include emergency calls or visits near the end of office hours, refusal to undergo appropriate examination, testing, or referral, repeated “loss” of prescriptions, tampering with prescriptions, and reluctance to provide prior medical records or contact information for other treating healthcare provider(s). “Doctor shopping” (visiting multiple prescribers to obtain additional prescriptions) is common among drug abusers and people suffering from untreated addiction. Preoccupation with achieving adequate pain relief can be appropriate behavior in a patient with poor pain control.

Abuse and addiction are separate and distinct from physical dependence and tolerance. Healthcare providers should be aware that addiction may not be accompanied by concurrent tolerance and symptoms of physical dependence in all addicts. In addition, abuse of opioids can occur in the absence of true addiction.

FIORINAL with CODEINE, like other opioids, can be diverted for non-medical use into illicit channels of distribution. Careful record-keeping of prescribing, including quantity, frequency, and renewal requests, as required by state and federal law, is strongly advised.

Proper assessment of the patient, proper prescribing practices, periodic re-evaluation of therapy, and proper dispensing and storage are appropriate measures that help to limit abuse of opioid drugs.

Risks Specific to Abuse of FIORINAL with CODEINE

FIORINAL with CODEINE is for oral use only. Abuse of FIORINAL with CODEINE poses a risk of overdose and death. The risk is increased with concurrent abuse of FIORINAL with CODEINE with alcohol and other central nervous system depressants.

Parenteral drug abuse is commonly associated with transmission of infectious diseases such as hepatitis and HIV.
Barbiturates may be habit-forming. Tolerance, psychological dependence, and physical dependence may occur especially following prolonged use of high doses of barbiturates. The average daily dose for the barbiturate addict is usually about 1,500 mg. As tolerance to barbiturates develops, the amount needed to maintain the same level of intoxication increases; tolerance to a fatal dosage, however, does not increase more than twofold. As this occurs, the margin between an intoxication dosage and fatal dosage becomes smaller. The lethal dose of a barbiturate is far less if alcohol is also ingested. Major withdrawal symptoms (convulsions and delirium) may occur within 16 hours and last up to 5 days after abrupt cessation of these drugs. Intensity of withdrawal symptoms gradually declines over a period of approximately 15 days. Treatment of barbiturate dependence consists of cautious and gradual withdrawal of the drug. Barbiturate-dependent patients can be withdrawn by using a number of different withdrawal regimens. One method involves initiating treatment at the patient’s regular dosage level and gradually decreasing the daily dosage as tolerated by the patient.

9.3 Dependence

Both tolerance and physical dependence can develop during chronic opioid therapy. Tolerance is the need for increasing doses of opioids to maintain a defined effect such as analgesia (in the absence of disease progression or other external factors). Tolerance may occur to both the desired and undesired effects of drugs, and may develop at different rates for different effects.

Physical dependence results in withdrawal symptoms after abrupt discontinuation or a significant dosage reduction. Physical dependence on opioids may lead to opioid antagonist activity (e.g., naloxone, nalmefene), mixed agonist/antagonist analgesics (e.g., pentazocine, butorphanol, nalbuphine), or partial agonists (e.g., buprenorphine). Physical dependence may not occur to a clinically significant degree until after several days to weeks of continued opioid usage.

FIORINAL with CODEINE should not be abruptly discontinued in a physically-dependent patient (see Dosage and Administration [2.3]). If FIORINAL with CODEINE is abruptly discontinued in a physically-dependent patient, a withdrawal syndrome may occur. Some or all of the following can characterize this syndrome: restlessness, lacrimation, rhinorrhea, yawning, perspiration, chills, myalgia, and mydriasis. Other signs and symptoms also may develop, including irritability, anxiety, backache, joint pain, weakness, abdominal cramps, incontinence, nausea, anorexia, vomiting, diarrhea, or increased blood pressure, respiratory rate, or heart rate.

Infants born to mothers physically dependent on opioids will also be physically dependent and may exhibit respiratory difficulties and withdrawal signs (see Use in Specific Populations [8.1, 8.2]).

10 OVERDOSE

Clinical Presentation

Acute overdose with FIORINAL with CODEINE can be manifested by respiratory depression, somnolence progressing to stupor or coma, skeletal muscle flaccidity, cold and clammy skin, constricted pupils, and, in some cases, pulmonary edema, bradycardia, hypotension, partial or complete airway obstruction, atypical snoring, and death. Marked mydriasis rather than miosis may be seen with hypoxia in overdose situations (see Clinical Pharmacology [12.2]).

Signs and Symptoms

Acute Barbiturate Poisoning:
Symptoms include drowsiness, confusion, and coma; respiratory depression; hypotension; hypovolemic shock.

Acute Aspirin Poisoning:
Symptoms include drowsiness, acid-base disturbances with development of metabolic acidosis; vomiting and abdominal pain; tinnitus, hyperthermia; hypoprothrombinemia; restlessness; delirium; convulsions.

Acute Caffeine Poisoning:
Symptoms include insomnia, restlessness, tremor, and delirium; tachycardia and extrasystoles.

Codeine:
Acute overdose with codeine can be manifested by respiratory depression, somnolence progressing to stupor or coma, skeletal muscle flaccidity, cold and clammy skin, constricted pupils, and, in some cases, pulmonary edema, bradycardia, hypotension, partial or complete airway obstruction, atypical snoring, and death. Marked mydriasis rather than miosis may be seen with hypoxia in overdose situations (see Clinical Pharmacology [12.2]).

Treatment of Overdose

In case of overdose, priorities are the reestablishment of a patent and protected airway and institution of assisted or controlled ventilation, if needed. Employ other supportive measures (including oxygen and vasopressors) in the management of circulatory shock and pulmonary edema as indicated. Cardiac arrest or arrhythmias will require advanced life-support techniques.

The opioid antagonists, naloxone or nalmefene, are specific antidotes to respiratory depression resulting from opioid overdose. For clinically significant respiratory or circulatory depression secondary to codeine phosphate overdose, administer an opioid antagonist. Opioid antagonists should not be administered in the absence of clinically significant respiratory or circulatory depression secondary to codeine overdose.

Because the duration of opioid reversal is expected to be less than the duration of action of codeine in FIORINAL with CODEINE, carefully monitor the patient until spontaneous respiration is reliably re-established. If the response to an opioid antagonist is suboptimal or only brief in nature, administer additional antagonist as directed by the product’s prescribing information.

In an individual physically dependent on opioids, administration of the recommended usual dosage of the antagonist will precipitate an acute withdrawal syndrome. The severity of the withdrawal symptoms experienced will depend on the degree of physical dependence and the dose of the antagonist administered. If a decision is made to treat serious respiratory depression in the physically dependent patient, administration of the antagonist should be begun with care and by titration with smaller than usual doses of the antagonist.

Treatment consists primarily of management of barbiturate intoxication, reversal of the effects of codeine, and the correction of the acid-base imbalance due to salicylism. Vomiting should be induced mechanically or with emetics in the conscious patient. Gastric lavage may be used if the pharynx and laryngeal reflexes are present and if less than 4 hours have elapsed since ingestion. A cuffed endotracheal tube should be inserted before gastric lavage of the unconscious patient and when

*Note: The text snippet appears to be incomplete and may require continuation or correction to provide a coherent and comprehensive representation of the document.*
necessary to provide assisted respiration. Diuresis, alkalization of the urine, and correction of electrolyte disturbances should be accomplished through administration of intravenous fluids such as 1% sodium bicarbonate and 5% dextrose in water.

Meticulous attention should be given to maintaining adequate pulmonary ventilation. The value of vasopressor agents such as Norepinephrine or Phenylephrine Hydrochloride in treating hypotension is questionable since they increase vasoconstriction and decrease blood flow. However, if prolonged support of blood pressure is required, Norepinephrine Bitartrate (Levophed®) may be given i.v. with the usual precautions and serial blood pressure monitoring. In severe cases of intoxication, peritoneal dialysis, hemodialysis, or exchange transfusion may be lifesaving. Hypoprothrombinemia should be treated with vitamin K, intravenously.

Methemoglobinemia over 30% should be treated with methylene blue by slow intravenous administration.

Naloxone, a narcotic antagonist, can reverse respiratory depression and coma associated with opioid overdose. Typically, a dose of 0.4 to 2 mg is given parenterally and may be repeated if an adequate response is not achieved. Since the duration of action of codeine may exceed that of the antagonist, the patient should be kept under continued surveillance and repeated doses of the antagonist should be administered as needed to maintain adequate respiration. A narcotic antagonist should not be administered in the absence of clinically significant respiratory or cardiovascular depression.

11 DESCRIPTION

FIORINAL with CODEINE (butalbital, aspirin, caffeine, and codeine phosphate, USP) is supplied in capsule form for oral administration.

Each capsule contains the following active ingredients:
- Butalbital, USP…………….50mg
- Aspirin, USP………………..325mg
- Caffeine, USP………………40mg
- Codeine phosphate, USP…...30mg

Butalbital (5-allyl-5-isobutylbarbituric acid) is a short- to intermediate-acting barbiturate. It has the following structural formula:

\[
C_{14}H_{16}N_{2}O_{3} \quad \text{molecular weight 224.26}
\]

Aspirin (benzoic acid, 2-(acetyloxy)-) is a nonsteroidal anti-inflammatory drug. It has the following structural formula:

\[
C_{9}H_{8}O_{4} \quad \text{molecular weight 180.16}
\]

Caffeine (1,3,7-trimethylxanthine), a methylxanthine, is a central nervous system stimulant. It has the following structural formula:

\[
C_{8}H_{10}N_{2}O_{2} \quad \text{molecular weight 194.19}
\]

Codeine phosphate (7,8-Didehydro-4,5α-epoxy-3-methoxy-17-methylmorphinan-6α-ol phosphate (1:1) (salt) hemihydrate) is an opioid agonist. It has the following structural formula:

\[
C_{18}H_{24}NO_5P \quad \text{methylene molecular weight 397.37}
\]

Ingredients: microcrystalline cellulose, pregelatinized starch, talc. Gelatin capsules contain D&C Yellow No. 10, FD&C Blue No. 1, FD&C Red No. 3, FD&C Yellow No. 6, gelatin, titanium dioxide. The capsules are printed with edible ink containing red iron oxide.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

Butalbital, a barbiturate, is a GABA_A receptor agonist and may inhibit excitatory AMPA receptors.

Aspirin is a nonsteroidal anti-inflammatory drug and a non-selective irreversible inhibitor of cyclooxygenases.

Caffeine is a methylxanthine and CNS stimulant. The exact mechanism with respect to the indication is not clear; however, the effects of caffeine may be due to antagonism of adenosine receptors.

Codeine is an opioid agonist relatively selective for the mu-opioid receptor, but with a much weaker affinity than morphine. The analgesic properties of codeine have been speculated to come from its conversion to morphine, although the exact mechanism of analgesic action remains unknown.

12.2 Pharmacodynamics
Effects on the Central Nervous System
Butalbital, a barbiturate, is a central nervous system (CNS) depressant that can produce sedation, respiratory depression, and euphoria. The potential impact of butalbital on painful stimuli is not clear and in some individuals barbiturates may increase reaction to painful stimuli.

Codeine produces respiratory depression by direct action on brain stem respiratory centers. The respiratory depression involves a reduction in the responsiveness of the brain stem respiratory centers to both increases in carbon dioxide tension and electrical stimulation.

Codeine causes miosis, even in total darkness. Pinpoint pupils are a sign of opioid overdose but are not pathognomonic (e.g., posterior lesions of hemorrhagic or ischemic origins may produce similar findings). Marked mydriasis rather than miosis may be seen due to hypoxia in overdose situations.

Aspirin works by inhibiting the body’s production of prostaglandins, including prostaglandins involved in inflammation. Prostaglandins cause pain sensations by stimulating muscle contractions and dilating blood vessels throughout the body. In the CNS, aspirin works on the hypothalamus heat-regulating center to reduce fever, however, other mechanisms may be involved.

Effects on the Gastrointestinal Tract and Other Smooth Muscle
Codeine causes a reduction in motility associated with an increase in smooth muscle tone in the antrum of the stomach and duodenum. Digestion of food in the small intestine is delayed and propulsive contractions are decreased. Propulsive peristaltic waves in the colon are decreased, while tone may be increased to the point of spasm, resulting in constipation. Other opioid-induced effects may include a reduction in biliary and pancreatic secretions, spasm of sphincter of Oddi, and transient elevations in serum amylase.

Aspirin can produce gastrointestinal injury (lesion, ulcers) through a mechanism that is not yet completely understood, but may involve a reduction in eicosanoid synthesis by the gastric mucosa. Decreased production of prostaglandins may compromise the defenses of the gastric mucosa and the activity of substances involved in tissue repair and ulcer healing.

Effects on the Cardiovascular System
Butalbital may decrease blood pressure and heart rate when administered at sedative and hypnotic doses.

Codeine produces peripheral vasodilation which may result in orthostatic hypotension or syncope. Manifestations of histamine release and/or peripheral vasodilation may include pruritus, flushing, red eyes, sweating, and/or orthostatic hypotension.

Aspirin affects platelet aggregation by irreversibly inhibiting prostaglandin cyclooxygenase. This effect lasts for the life of the platelet and prevents the formation of the platelet aggregating factor, thromboxane A2. Nonacetylated salicylates do not inhibit this enzyme and have no effect on platelet aggregation. At somewhat higher doses, aspirin reversibly inhibits the formation of prostaglandin 12 (prostacyclin), which is an arterial vasodilator and inhibits platelet aggregation.

Effects on the Endocrine System
Opioids inhibit the secretion of adrenocorticotropic hormone (ACTH), cortisol, and luteinizing hormone (LH) in humans. They also stimulate prolactin, growth hormone (GH) secretion, and pancreatic secretion of insulin and glucagon.

Chronic use of opioids may influence the hypothalamic-pituitary-gonadal axis, leading to androgen deficiency that may manifest as low libido, impotence, erectile dysfunction, amenorrhea, or infertility. The causal role of opioids in the clinical syndrome of hypogonadism is unknown because the various medical, physical, lifestyle, and psychological stressors that may influence gonadal hormone levels have not been adequately controlled for in studies conducted to date.

Effects on the Immune System
Opioids have been shown to have a variety of effects on components of the immune system in vitro and animal models. The clinical significance of these findings is unknown. Overall, the effects of opioids appear to be modestly immunosuppressive.

Concentration-Efficacy Relationships
The minimum effective analgesic concentration will vary widely among patients, especially among patients who have been previously treated with potent agonist opioids. The minimum effective analgesic concentration of codeine for any individual patient may increase over time due to an increase in pain, the development of a new pain syndrome and/or the development of analgesic tolerance.

Concentration-Adverse Reaction Relationships
There is a relationship between increasing codeine plasma concentration and increasing frequency of dose-related opioid adverse reactions such as nausea, vomiting, CNS effects, and respiratory depression. In opioid-tolerant patients, the situation may be altered by the development of tolerance to opioid-related adverse reactions.

12.3 Pharmacokinetics
Bioavailability:
The bioavailability of the components of the fixed combination of FIORINAL with CODEINE is identical to their bioavailability when Fiorinal (Butalbital, Aspirin, and Caffeine Capsules,) and codeine are administered separately in equivalent molar doses. The behavior of the individual components is described below.

Aspirin
Absorption
The systemic availability of aspirin after an oral dose is highly dependent on the dosage form, the presence of food, the gastric emptying time, gastric pH, antacids, buffering agents, and particle size. These factors affect not necessarily the extent of absorption of total salicylates but more the stability of aspirin prior to absorption.

Distribution
During the absorption process and after absorption, aspirin is mainly hydrolyzed to salicylic acid and distributed to all body tissues and fluids, including fetal tissues, breast milk, and the central nervous system (CNS). Highest concentrations are found in plasma, liver, renal cortex, heart, and lung. In plasma, about 50%-80% of the salicylic acid and its metabolites are loosely bound to plasma protein.

Elimination
Metabolism
The biotransformation of aspirin occurs primarily in the hepatocytes. The major metabolites are salicylic acid (75%), the phenolic and acyl glucuronides of salicylate (15%), and gentisic and...
gentisic acid (1%). The bioavailability of the aspirin component of FIORINAL with CODEINE is equivalent to that of a solution except for a slower rate of absorption. A peak concentration of 8.8 mcg/mL was obtained at 40 minutes after a 650 mg dose.

**Excretion**

The clearance of total salicylates is subject to saturable kinetics; however, first-order elimination kinetics are still a good approximation for doses up to 650 mg. The plasma half-life for aspirin is about 12 minutes and for salicylic acid and/or total salicylates is about 3 hours.

The elimination of therapeutic doses is through the kidneys either as salicylic acid or other biotransformation products. The renal clearance is greatly augmented by an alkaline urine as is produced by concurrent administration of sodium bicarbonate or potassium citrate.

**Caffeine**

**Absorption**

Caffeine is well absorbed from the gastrointestinal tract. The bioavailability of the caffeine component of FIORINAL with CODEINE is equivalent to that of a solution except for a decrease in the rate of absorption. A peak concentration of 2,020 ng/mL is obtained at about 1.5 hours after a 100 mg dose.

**Distribution**

Caffeine is distributed in all body tissues and fluids, including the CNS, fetal tissues, and breast milk. Caffeine crosses the blood-brain barrier, and is found in fetal tissue and breast milk. The plasma concentration does not correlate with brain concentration or relief of pain; however, caffeine is not bound to plasma proteins and does not accumulate in body tissues.

**Elimination**

**Metabolism**

About 70-80% of administered dose of caffeine is metabolized by conjugation with glucuronic acid to caffeine-6-glucuronide (C6G) and via O-demethylation to morphine (about 5-10%) and N-demethylation to norcodeine (about 10%) respectively. UDP-glucuronosyltransferase (UGT) 2B7 and 2B4 are the major enzymes mediating glucuronidation of caffeine to C6G. Cytochrome P450 2D6 is the major enzyme responsible for conversion of caffeine to morphine and P450 3A4 is the major enzyme mediating conversion of caffeine to norcodeine. Morphine and norcodeine are further metabolized by conjugation with glucuronic acid. The glucuronide metabolites of morphine are morphine-3-glucuronide (M3G) and morphine-6-glucuronide (M6G). Morphine and M6G are known to have analgesic activity in humans. The analgesic activity of C6G in humans is unknown. Norcodeine and M3G are generally not considered to possess analgesic properties.

**Excretion**

The plasma half-life is about 2.9 hours. The elimination of caffeine is primarily via the kidneys, and about 90% of an oral dose is excreted by the kidneys within 24 hours of dosing. The urinary secretion products consist of free and glucuronide-conjugated caffeine (about 70%), free and conjugated norcodeine (about 10%), free and conjugated morphine (about 10%), normorphine (4%), and hydrocodone (1%). The remainder of the dose is excreted in the feces.

**Butalbital**

**Absorption**

Butalbital is well absorbed from the gastrointestinal tract. The bioavailability of the butalbital component of FIORINAL with CODEINE is equivalent to that of a solution except for a decrease in the rate of absorption. A peak concentration of 2.020 ng/mL is obtained at about 1.5 hours after a 100 mg dose.

**Distribution**

Butalbital is expected to distribute to most of the tissues in the body. Barbiturates, in general, may appear in breast milk and readily cross the placental barrier. They are bound to plasma and tissue proteins to a varying degree and binding increases directly as a function of lipid solubility. The in vitro plasma protein binding of butalbital is 45% over the concentration range of 0.5 to 20 mcg/mL. This falls within the range of plasma protein binding (20% to 45%) reported with other barbiturates such as phenobarbital, pentobarbital, and secobarbital sodium. The plasma-to-blood concentration ratio was almost unity indicating that there is no preferential distribution of butalbital into either plasma or blood cells.

**Elimination**

Elimination of butalbital is primarily via the kidney (59% to 88% of the dose) as unchanged drug or metabolites. The plasma half-life is about 35 hours. Urinary excretion products included parent drug (about 3.6% of the dose), 5-isobutyl-5-(3-hydroxy-2-methyl-1-propyl) barbituric acid (about 24% of the dose), 5-allyl-5-(3-hydroxy-2-methyl-1-propyl) barbituric acid (about 4.8% of the dose), products with the barbituric acid ring hydrolyzed with excretion of urea (about 14% of the dose), as well as unidentified materials. Of the material excreted in the urine, 32% was conjugated.

**Codeine**

**Absorption**

Codeine is readily absorbed from the gastrointestinal tract. The bioavailability of the codeine component of FIORINAL with CODEINE is equivalent to that of a solution. Peak concentrations of 198 ng/mL were obtained at 1 hour after a 60 mg dose. At therapeutic doses, the analgesic effect reaches a peak within 2 hours and persists between 4 and 6 hours.

**Distribution**

It is rapidly distributed from the intravascular spaces to the various body tissues, with preferential uptake by parenchymatous organs such as the liver, spleen, and kidney. Codeine crosses the blood-brain barrier, and is found in fetal tissue and breast milk. The plasma concentration does not correlate with brain concentration or relief of pain; however, codeine is not bound to plasma proteins and does not accumulate in body tissues.

**Elimination**

**Metabolism**

About 70-80% of administered dose of codeine is metabolized by conjugation with glucuronic acid to codeine-6-glucuronide (C6G) and via O-demethylation to morphine (about 5-10%) and N-demethylation to norcodeine (about 10%) respectively. UDP-glucuronosyltransferase (UGT) 2B7 and 2B4 are the major enzymes mediating glucuronidation of codeine to C6G. Cytochrome P450 2D6 is the major enzyme responsible for conversion of codeine to morphine and P450 3A4 is the major enzyme mediating conversion of codeine to norcodeine. Morphine and norcodeine are further metabolized by conjugation with glucuronic acid. The glucuronide metabolites of morphine are morphine-3-glucuronide (M3G) and morphine-6-glucuronide (M6G). Morphine and M6G are known to have analgesic activity in humans. The analgesic activity of C6G in humans is unknown. Norcodeine and M3G are generally not considered to possess analgesic properties.

**Excretion**

The plasma half-life is about 2.9 hours. The elimination of codeine is primarily via the kidneys, and about 90% of an oral dose is excreted by the kidneys within 24 hours of dosing. The urinary secretion products consist of free and glucuronide-conjugated codeine (about 70%), free and conjugated norcodeine (about 10%), free and conjugated morphine (about 10%), normorphine (4%), and hydrocodone (1%). The remainder of the dose is excreted in the feces.

**Codeine**

**Absorption**

Codeine is readily absorbed from the gastrointestinal tract. The bioavailability of the codeine component of FIORINAL with CODEINE is equivalent to that of a solution except for a decrease in the rate of absorption. A peak concentration of 2,020 ng/mL is obtained at about 1.5 hours after a 100 mg dose.

**Distribution**

Codeine is distributed in all body tissues and fluids, including the CNS, fetal tissues, and breast milk. The plasma concentration does not appear in breast milk and readily cross the placental barrier. They are bound to plasma and tissue proteins to a varying degree and binding increases directly as a function of lipid solubility. The in vitro plasma protein binding of codeine is 45% over the concentration range of 0.5 to 20 mcg/mL. This falls within the range of plasma protein binding (20% to 45%) reported with other barbiturates such as phenobarbital, pentobarbital, and secobarbital sodium. The plasma-to-blood concentration ratio was almost unity indicating that there is no preferential distribution of butalbital into either plasma or blood cells.

**Elimination**

Elimination of butalbital is primarily via the kidney (59% to 88% of the dose) as unchanged drug or metabolites. The plasma half-life is about 35 hours. Urinary excretion products included parent drug (about 3.6% of the dose), 5-isobutyl-5-(3-hydroxy-2-methyl-1-propyl) barbituric acid (about 24% of the dose), 5-allyl-5-(3-hydroxy-2-methyl-1-propyl) barbituric acid (about 4.8% of the dose), products with the barbituric acid ring hydrolyzed with excretion of urea (about 14% of the dose), as well as unidentified materials. Of the material excreted in the urine, 32% was conjugated.
Of the 70% of the dose that has been recovered in the urine, only 3% was unchanged drug. The plasma half-life is about 3 hours.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Carcinogenesis

Long-term studies in animals to evaluate the carcinogenic potential of the combination of butalbital, aspirin, caffeine, and codeine or butalbital alone have not been conducted.

Administration of aspirin for 68 weeks at 0.5 percent in the feed of rats was not carcinogenic. Two-year carcinogenicity studies with codeine sulfate have been conducted in F344/N rats and B6C3F1 mice. There was no evidence of carcinogenicity in male and female rats, respectively, at dietary doses up to 70 and 80 mg/kg/day of codeine sulfate (approximately 4 times the maximum recommended daily dose of 180 mg/day for adults on a mg/m² basis) for two years. Similarly, there was no evidence of carcinogenicity in male and female mice at dietary doses up to 400 mg/kg/day of codeine sulfate (approximately 10 times the maximum recommended daily dose of 180 mg/day for adults on a mg/m² basis) for two years.

In a 2-year study in Sprague-Dawley rats, caffeine (as caffeine base) administered in drinking water was not carcinogenic in male rats at doses up to 102 mg/kg or in female rats at doses up to 170 mg/kg (approximately 4 and 7 times, respectively, the maximum human daily dose on a mg/m² basis). In an 18-month study in C57BL/6 mice, no evidence of tumorigenicity was seen at dietary doses up to 55 mg/kg (equivalent to the MHDD on a mg/m² basis).

Mutagenesis

There are no genetic toxicology data for butalbital. Codeine sulfate was not mutagenic in the in vitro bacterial reverse mutation assay or clastogenic in the in vitro Chinese hamster ovary cell chromosome aberration assay. Aspirin is not mutagenic in the Salmonella assay; however, aspirin did induce chromosome aberrations in cultured human fibroblasts. Caffeine (as caffeine base) increased the sister chromatid exchange (SCE) SCE/cell metaphase (exposure time dependent) in an in vivo mouse metaphase analysis. Caffeine also potentiated the genotoxicity of known mutagens and enhanced the micronucleus formation (5-fold) in folate-deficient mice. However, caffeine did not increase chromosomal aberrations in vitro Chinese hamster ovary cell (CHO) and human lymphocyte assays and was not mutagenic in an in vitro CHO/hypoxanthine guanine phosphoribosyltransferase (HGPRT) gene mutation assay, except at cytotoxic concentrations. In addition, caffeine was not clastogenic in an in vivo mouse micronucleus assay. Caffeine was negative in the in vitro bacterial reverse mutation assay (Ames test).

Impairment of Fertility

No adequate studies have been conducted in animals to characterize the impact of the combination of butalbital, aspirin, caffeine, and codeine on fertility. There are also no data on butalbital alone or codeine alone.

Aspirin inhibits ovulation in rats. Caffeine (as caffeine base) administered to male rats at 50 mg/kg/day subcutaneously (2 times the MHDD on a mg/m² basis) for 4 days prior to mating with untreated females, caused decreased male reproductive performance in addition to causing embryotoxicity. In addition, long-term exposure to high oral doses of caffeine (3 g over 7 weeks) was toxic to rat testes as manifested by spermatogenic cell degeneration.

14 CLINICAL TRIALS

Evidence supporting the efficacy of FIORINAL with CODEINE is derived from 2 multi-clinic trials that compared patients with tension headache randomly assigned to 4 parallel treatments: FIORINAL with CODEINE, codeine, Fiorinal (butalbital, aspirin, and caffeine capsules, USP), and placebo. Response was assessed over the course of the first 4 hours of each of 2 distinct headaches, separated by at least 24 hours. FIORINAL with CODEINE proved statistically significantly superior to each of its components (Fiorinal, codeine) and to placebo on measures of pain relief.

Evidence supporting the efficacy and safety of FIORINAL with CODEINE in the treatment of multiple recurrent headaches is unavailable. Caution in this regard is required because codeine and butalbital are habit-forming and potentially abusable.

16 HOW SUPPLIED/STORAGE AND HANDLING

FIORINAL with CODEINE (Butalbital, Aspirin, Caffeine, and Codeine Phosphate Capsules, USP)

Blue cap with a yellow body. Cap is imprinted twice with “FIORINAL” and “CODEINE” in red. Body is imprinted twice with “WATSON 956” in red.

High density polyethylene bottles of 100 capsules are supplied with child-resistant closures. (NDC 52544-956-01)

Store and Dispense

Below 25°C (77°F); tight container. Protect from moisture. Rx only

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide).

Addiction, Abuse, and Misuse

Inform patients that the use of FIORINAL with CODEINE, even when taken as recommended, can result in addiction, abuse, and misuse, which can lead to overdose and death (see Warnings and Precautions (5.1)). Instruct patients not to share FIORINAL with CODEINE with others and to take steps to protect FIORINAL with CODEINE from theft or misuse.

Life-Threatening Respiratory Depression

Inform patients of the risk of life-threatening respiratory depression, including information that the risk is greatest when starting FIORINAL with CODEINE or when the dosage is increased, and that it can occur even at recommended dosages (see Warnings and Precautions (5.2)). Advise patients how to recognize respiratory depression and to seek medical attention if breathing...
Inform patients that accidental ingestion, especially by children, may result in respiratory depression or death. Instruct patients to take steps to store FIORINAL with CODEINE securely and to properly dispose of unused FIORINAL with CODEINE in accordance with the local state guidelines and/or regulations.

Inform patients and caregivers that potentially fatal additive effects may occur if FIORINAL with CODEINE is used with benzodiazepines or other CNS depressants, including alcohol, and not to use these concomitantly unless supervised by a health care provider [see Warnings and Precautions (5.3), Drug Interactions (7)].

Inform patients not to take FIORINAL with CODEINE while using any drugs that inhibit monoamine oxidase. Patients should not start MAOIs while taking FIORINAL with CODEINE [see Drug Interactions (7)].

Inform patients that opioid concomitant administration of serotonergic drugs. Warn patients of the symptoms of serotonin syndrome and to seek medical attention right away if symptoms develop. Instruct patients to inform their healthcare providers if they are taking, or plan to take serotonergic medications. [see Drug Interactions (7)].

Inform patients how to properly take FIORINAL with CODEINE. [see Dosage and Administration (2.2)]. Patients should take the drug only for as long as it is prescribed, in the amounts prescribed, and no more frequently than prescribed.

Inform patients that FIORINAL with CODEINE may cause orthostatic hypotension and syncope. Instruct patients how to recognize symptoms of low blood pressure and how to reduce the risk of serious consequences should hypotension occur (e.g., sit or lie down, carefully rise from a sitting or lying position) [see Warnings and Precautions (5.10)].

Inform patients that anaphylaxis has been reported with ingredients contained in FIORINAL with CODEINE. Advise patients how to recognize such a reaction and when to seek medical attention [see Contraindications (4), Adverse Reactions (6)].

Inform patients that FIORINAL with CODEINE may cause reduced fertility. It is not known whether these effects on fertility are reversible [see Use in Specific Populations (8.3)].

Instruct patients about the signs and symptoms of bleeding. Tell patients to notify their physician if they are prescribed any drug which may increase risk of bleeding.

Counsel patients who consume three or more alcoholic drinks daily about the bleeding risks involved with chronic, heavy alcohol use while taking aspirin [see Warnings and Precautions (5.16)].

Inform patients that FIORINAL with CODEINE may impair the ability to perform potentially hazardous activities such as driving a car or operating heavy machinery. Advise patients not to perform such tasks until they know how they will react to the medication [see Warnings and Precautions (5.15)].

Advise patients of the potential for severe constipation, including management instructions and when to seek medical attention [see Adverse Reactions (6)].
FIORINAL with CODEINE is:
- A strong prescription pain medicine that contains an opioid (narcotic) that is indicated for the relief of the symptom complex of tension (or muscle contraction) headache, when other pain treatments such as non-opioid pain medicines do not treat your pain well enough or you cannot tolerate them.
- An opioid pain medicine that can put you at risk for overdose and death. Even if you take your dose correctly as prescribed you are at risk for opioid addiction, abuse, and misuse that can lead to death.

Important information about FIORINAL with CODEINE:
- Get emergency help right away if you take too much FIORINAL with CODEINE (overdose). When you first start taking FIORINAL with CODEINE, when your dose is changed, or if you take too much (overdose), serious or life-threatening breathing problems that can lead to death may occur.
- Taking FIORINAL with CODEINE with other opioid medicines, benzodiazepines, alcohol, or other central nervous system depressants (including street drugs) can cause severe drowsiness, decreased awareness, breathing problems, coma, and death.
- Never give anyone else your FIORINAL with CODEINE. They could die from taking it. Store FIORINAL with CODEINE away from children and in a safe place to prevent stealing or abuse. Selling or giving away FIORINAL with CODEINE is against the law.

Important Information Guiding Use in Pediatric Patients:
- Do not give FIORINAL with CODEINE to a child younger than 12 years of age.
- Do not give FIORINAL with CODEINE to a child younger than 18 years of age after surgery to remove the tonsils and/or adenoids.
- Avoid giving FIORINAL with CODEINE to children between 12 to 18 years of age who have risk factors for breathing problems such as obstructive sleep apnea, obesity, or underlying lung problems.

Do not give FIORINAL with CODEINE to a child or teenager with a viral illness. Reye syndrome, a life-threatening condition, can happen when aspirin (an ingredient in FIORINAL with CODEINE) is used in children and teenagers who have certain viral illnesses.

Do not take FIORINAL with CODEINE if you have:
- severe asthma, trouble breathing, or other lung problems.
- a bowel blockage or have narrowing of the stomach or intestines.
- known allergy to nonsteroidal anti-inflammatory drug products (NSAIDs)
- a rare disorder in which your blood doesn’t clot normally (hemophilia)

Before taking FIORINAL with CODEINE, tell your healthcare provider if you have a history of:
- head injury, seizures
- problems urinating
- liver, kidney, thyroid problems
- pancreas or gallbladder problems
- abuse of street or prescription drugs, alcohol addiction, or mental health problems.
- have been told by your healthcare provider that you are a “rapid metabolizer” of certain medicines

Tell your healthcare provider if you are:
- pregnant or planning to become pregnant. FIORINAL with CODEINE may harm your unborn baby. Prolonged use of FIORINAL with CODEINE during pregnancy can cause withdrawal symptoms in your newborn baby that could be life-threatening if not recognized and treated.
- breastfeeding. Not recommended; may harm your baby.
- taking prescription or over-the-counter medicines, vitamins, or herbal supplements. Taking FIORINAL with CODEINE with certain other medicines can cause serious side effects that could lead to death.

When taking FIORINAL with CODEINE:
- Do not change your dose. Take FIORINAL with CODEINE exactly as prescribed by your healthcare provider. Use the lowest dose possible for the shortest time needed.
- Take your prescribed dose of 1 or 2 capsules every 4 hours. Total daily dosage should not exceed 6 capsules. Do not take more than your prescribed dose. If you miss a dose, take your next dose at your usual time.
- Call your healthcare provider if the dose you are taking does not control your pain.
- If you have been taking FIORINAL with CODEINE regularly, do not stop taking FIORINAL with CODEINE without talking to your healthcare provider.
- After you stop taking FIORINAL with CODEINE, dispose the unused FIORINAL with CODEINE in accordance with the local state guidelines and/or regulations.

While taking FIORINAL with CODEINE DO NOT:
- Drive or operate heavy machinery, until you know how FIORINAL with CODEINE affects you. FIORINAL with CODEINE can make you sleepy, dizzy, or lightheaded.
- Drink alcohol or use prescription or over-the-counter medicines that contain alcohol. Using products containing alcohol during treatment with FIORINAL with CODEINE may cause you to overdose and die.
