TPN ELECTROLYTES—sodium chloride, calcium chloride, potassium chloride, magnesium chloride, and sodium acetate anhydrous injection, solution, concentrate
Hospira, Inc.

----------

TPN* Electrolytes

Multiple Electrolyte Additive
Contains No Phosphate
Rx only

Concentrated Solution — For intravenous use only after dilution and thorough mixing.
Formulated to provide additive electrolytes for patients receiving total parenteral nutrition.

Plastic Vial

DESCRIPTION

TPN Electrolytes (multiple electrolyte additive) is a sterile, nonpyrogenic, concentrated solution of intra- and extracellular ions for intravenous infusion after dilution as a maintenance electrolyte replenisher only. It contains no phosphate and no bacteriostat, antimicrobial agent or added buffer. The pH is 6.6 (6.0 to 7.5). May contain hydrochloric acid for pH adjustment. The osmolar concentration is 6.2 mOsmol/mL (calc.).

*Total Parenteral Nutrition

Ingredients and ion constituents of the solution are as follows:

Sodium Chloride, USP is chemically designated NaCl, a white crystalline compound freely soluble in water.

Calcium Chloride, USP dihydrate is chemically designated CaCl₂ • 2H₂O, white, odorless fragments or granules, freely soluble in water.

Potassium Chloride, USP is chemically designated KCl, a white granular powder freely soluble in water.
Magnesium Chloride, USP hexahydrate is chemically designated MgCl$_2$ • 6H$_2$O, deliquescent crystals very soluble in water.

Sodium Acetate, USP anhydrous is chemically designated C$_2$H$_3$NaO$_2$, a hygroscopic powder very soluble in water.

Water for Injection, USP is chemically designated H$_2$O.

The semi-rigid container is fabricated from a specially formulated polyolefin. It is a copolymer of ethylene and propylene. The safety of the plastic has been confirmed by tests in animals according to USP biological standards for plastic containers. The container requires no vapor barrier to maintain the proper drug concentration.

**CLINICAL PHARMACOLOGY**

TPN Electrolytes (multiple electrolyte additive) helps to maintain normal cellular metabolism during TPN (total parenteral nutrition). Providing electrolytes in appropriate amounts prevents deficiency symptoms which otherwise would occur in their absence.

**Cations:** Sodium is the principal extracellular cation; it helps maintain motor nerve depolarization, proper fluid balance and normal renal metabolism. Potassium is the principal intracellular cation; it helps transport dextrose across the cell membrane and contributes to normal renal function. Magnesium is an important cofactor for enzymatic reactions and helps to maintain normal CNS (central nervous system) activity and amino acid utilization. Calcium participates in muscle contraction, blood coagulation and helps maintain normal neuromuscular function.

**Anions:** Chloride is the principal extracellular anion which, along with bicarbonate, is involved in maintaining proper anion balance. Acetate is an important metabolic intermediate in the tricarboxylic acid cycle and is a bicarbonate alternate.

The distribution and excretion of sodium (Na$^+$) and chloride (Cl$^-$) are largely under the control of the kidney which maintains a balance between intake and output.

Approximately 80% of body calcium (Ca$^{++}$) is excreted in the feces as insoluble salts; urinary excretion accounts for the remaining 20%.

Potassium (K$^+$) is found in low concentration in the plasma and extracellular fluids (3.5 to 5.0 mEq/liter in a healthy adult). Normally about 80% to 90% of the potassium intake is excreted in the urine, the remainder in the stools and to a small extent, in the perspiration. The kidney does not conserve potassium well so that during fasting or in patients on a potassium-free diet, potassium loss from the body continues resulting in potassium depletion.

Magnesium (Mg$^{++}$) is the second most plentiful intracellular cation. Normal plasma concentration ranges from 1.5 to 2.5 or 3.0 mEq per liter. Magnesium is excreted solely by the kidney at a rate proportional to the plasma concentration and glomerular filtration.

Acetate (CH$_3$COO$^-$) provides bicarbonate (HCO$_3^-$) by metabolic conversion in the liver. This has been shown to proceed readily even in the presence of severe liver disease.

**INDICATIONS AND USAGE**

TPN Electrolytes (multiple electrolyte additive) is indicated for use as a supplement to nutritional solutions containing concentrated dextrose and amino acids delivered by central venous infusion, to help maintain electrolyte homeostasis in adult patients.

**CONTRAINDICATIONS**

TPN Electrolytes (multiple electrolyte additive) is contraindicated in pathological conditions where
additives of potassium, sodium, calcium, magnesium or chloride could be clinically deleterious, e.g.,
anuria, hyperkalemia, heart block or myocardial damage and severe edema due to cardiovascular, renal
or hepatic failure.

**WARNINGS**

CONCENTRATED, HYPERTONIC, ADDITIVE SOLUTION. **Must be diluted** in TPN solution prior
to administration.

CONTAINS NO PHOSPHATE. Patients receiving TPN solutions containing concentrated dextrose
require additive phosphate, in addition to TPN Electrolytes. Between 10 and 15 mM (310 to 465 mg)
phosphorus are physically compatible with as much as 10 to 12 mEq calcium in the same admixture. The
phosphate supplement should first be added to the amino acid or dextrose bottle and diluted well to
avoid precipitation with calcium.

CONTAINS 20 mEq of POTASSIUM. The potassium content of other additives, such as potassium
phosphate or potassium-containing antibiotics, must be considered in the context of total potassium
delivered. TPN patients usually require 30 to 50 mEq of potassium per liter of TPN solution containing
concentrated (20—25%) dextrose.

NOT INTENDED FOR PEDIATRIC USE.

Solutions containing sodium ions should be used with great care, if at all, in patients with congestive
heart failure, severe renal insufficiency and in clinical states in which there exists edema with sodium
retention.

Solutions which contain potassium ions should be used with great care, if at all, in patients with
hyperkalemia, severe renal failure and in conditions in which potassium retention is present.

In patients with diminished renal function, administration of solutions containing sodium or potassium
ions may result in sodium or potassium retention.

Solutions containing acetate ions should be used with great care in patients with metabolic or
respiratory alkalosis. Acetate should be administered with great care in those conditions in which there
is an increased level or an impaired utilization of this ion, such as severe hepatic insufficiency.

*Warning:* This product contains aluminum that may be toxic. Aluminum may reach toxic levels with
prolonged parenteral administration if kidney function is impaired. Premature neonates are particularly at
risk because their kidneys are immature, and they require large amounts of calcium and phosphate
solutions, which contain aluminum.

Research indicates that patients with impaired kidney function, including premature neonates, who
receive parenteral levels of aluminum at greater than 4 to 5 mcg/kg/day accumulate aluminum levels
associated with central nervous system and bone toxicity. Tissue loading may occur at even lower rates
of administration.

**PRECAUTIONS**

Do not administer unless solution is clear and seal is intact. Discard unused portion.

Blood levels of sodium, potassium, calcium, magnesium, phosphorus and chloride should be monitored
frequently during TPN (total parenteral nutrition). Significant deviations from normal may justify further
supplementation or substitution of individual electrolyte additives (in place of TPN Electrolytes) to
tailor the electrolyte supplement to meet individual patient requirements.

In patients with renal dysfunction or cardiovascular insufficiency, especially in elderly or postsurgical
patients, consider the potential effects of sodium (35 mEq) and potassium (20 mEq) present in TPN
Electrolytes.
Extraordinary electrolyte losses are not necessarily corrected by TPN Electrolytes. In protracted vomiting or diarrhea or in patients with fistula drainage or nasogastric suction, separate replacement therapy may be necessary, based upon analysis of losses sustained.

Caution must be exercised in the administration of parenteral fluids, especially those containing sodium ions, to patients receiving corticosteroids or corticotropin.

Solutions containing acetate ions should be used with caution as excess administration may result in metabolic alkalosis.

Pregnancy

Animal reproduction studies have not been conducted with TPN Electrolytes. It is also not known whether TPN Electrolytes can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. TPN Electrolytes should be given to a pregnant woman only if clearly needed.

Geriatric Use

An evaluation of current literature revealed no clinical experience identifying differences in response between elderly and younger patients. In general, dose selection for an elderly patient should be cautious, usually starting at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease or other drug therapy.

Sodium ions and phosphorus are known to be substantially secreted by the kidney, and the risk of toxic reactions may be greater in patients with impaired renal function. Because elderly patients are more likely to have decreased renal function, care should be taken in dose selection, and it may be useful to monitor renal function.

Adverse Reactions

Symptoms may result from an excess or deficit of one or more of the ions present in TPN Electrolytes. Therefore, frequent monitoring of electrolyte blood levels is recommended. Sodium excess can cause edema and exacerbation of congestive heart failure. Excess potassium can cause deviations from the normal ECG (electrocardiogram). Potassium deficits can impair neuromuscular function, causing muscle weakness or frank paralysis, intestinal dilatation and ileus. Calcium deficits can produce neuromuscular hyperexcitability, ranging from paresthesias, cramps and laryngospasm to tetany and grand mal seizures. Depressed calcium levels can accompany administration of parenteral phosphorous or large amounts of albumin. Magnesium deficiency can precipitate neuromuscular dysfunction, hyperirritability, psychotic behavior, tachycardia and hypertension. Magnesium excess can cause muscle weakness, ECG changes, sedation and mental confusion.

Drug Abuse and Dependence

None known.

Overdosage

In the event of overhydration or solute overload, re-evaluate the patient and institute appropriate corrective measures. See WARNINGS and PRECAUTIONS.

Dosage and Administration

One 20 mL volume of TPN Electrolytes (multiple electrolyte additive) is added to each liter of amino acid/dextrose solution. Alternatively, the TPN Electrolytes can be added to the bottle of amino acids or concentrated dextrose, to permit addition of the necessary phosphate additive to the remaining bottle. This latter technique helps avoid physical incompatibilities between calcium and phosphorus.
potassium phosphate additive is recommended for addition to nutritional solutions containing TPN Electrolytes. Between 10 and 30 mEq of potassium (as phosphate) should be added per liter of TPN solution, to augment the 20 mEq of potassium provided by TPN Electrolytes.

Between two and three liters of TPN solution with added TPN Electrolytes are usually administered daily to adults. Solutions are given continuously over the entire 24-hour period at a constant rate, ranging from 83 to 125 mL/hour. TPN solutions containing TPN Electrolytes and concentrated dextrose are administered intravenously, through a central venous catheter.

Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration, whenever solution and container permit. See PRECAUTIONS.

HOW SUPPLIED

TPN Electrolytes (multiple electrolyte additive) is supplied in the following single-dose delivery system:

<table>
